ABSTRACT

Dysfunctional hepatic lipid metabolism is a cause of non-alcoholic fatty liver disease

(NAFLD), the most common chronic liver disorder worldwide, and is closely associated

with insulin resistance and type 2 diabetes (T2D). ELOVL fatty acid elongase 6

(Elovl6) is responsible for converting C16 saturated and monounsaturated fatty acids

(FAs) into C18 species. We have previously shown that Elovl6 contributes to

obesity-induced insulin resistance by modifying hepatic C16/C18-related FA

composition. To define the precise molecular mechanism by which hepatic Elovl6

affects energy homeostasis and metabolic disease, we generated liver-specific Elovl6

knockout (LKO) mice. Unexpectedly, LKO mice were not protected from high-fat

diet-induced insulin resistance. Instead, LKO mice exhibited higher insulin sensitivity

than controls when consuming a high-sucrose diet (HSD), which induces lipogenesis.

Hepatic patatin-like phospholipase domain-containing protein 3 (Pnpla3) expression

was downregulated in LKO mice, and adenoviral Pnpla3 restoration reversed the

enhancement in insulin sensitivity in HSD-fed LKO mice. Lipidomic analyzes showed

that the hepatic ceramide(d18:1/18:0) content was lower in LKO mice, which may

explain the effect on insulin sensitivity. Ceramide(d18:1/18:0) enhances protein

7

phosphatase 2A (PP2A) activity by interfering with the binding of PP2A to its biological inhibitor I2PP2A, leading to Akt dephosphorylation. Its production involves the formation of an Elovl6-ceramide synthase 4 (CerS4) complex in the endoplasmic reticulum (ER) and a Pnpla3-CerS4 complex on lipid droplets (LDs). Consistent with this, liver-specific Elovl6 deletion in *ob/ob* mice reduced both hepatic ceramide(d18:1/18:0) and PP2A activity, and ameliorated insulin resistance. *Conclusion:* Our study demonstrates the key role of hepatic Elovl6 in the regulation of the acyl-chain composition of ceramide, and that C18:0-ceramide is a potent regulator of hepatic insulin signaling linked to Pnpla3-mediated NAFLD.

8

INTRODUCTION

Non-alcoholic fatty liver disease (NAFLD), characterized by excessive triacylglycerol (TAG) accumulation in hepatocytes, is recognized as a hepatic phenotype of the metabolic syndrome (1). A large majority of obese and diabetic individuals develop NAFLD, but it is also a risk factor for various other conditions, including insulin resistance, hyperlipidemia, and type 2 diabetes (T2D) (2, 3). Furthermore, non-alcoholic steatohepatitis (NASH), a severe form of NAFLD characterized by hepatocellular damage, lobular inflammation, abnormal glucose tolerance, and fibrosis, can progress to cirrhosis and hepatocellular carcinoma (4, 5).

Chronic and/or excess consumption of carbohydrates and saturated fatty acids (FAs) is associated with the development of hepatic insulin resistance (6, 7). Hepatic insulin resistance promotes aberrant glucose production, *de novo* lipogenesis (DNL), atherogenic dyslipidemia, and NAFLD, which are major risk factors for T2D and cardiovascular disease (8, 9). There are few effective therapies for hepatic insulin resistance or obesity, and the development of novel therapeutics necessitates a better understanding of the mechanistic relationship between obesity and NAFLD.

Elongation and desaturation are central steps in the *de novo* synthesis of long-chain

FAs, and length and saturation are critical determinants of FA function and metabolic

fate (10). ELOVL fatty acid elongase 6 (Elovl6) is a microsomal enzyme that is

involved in the elongation of C16 saturated and monounsaturated FAs to form C18 FAs

(11, 12). Loss of Elovl6 function reduces stearate (C18:0) and oleate (C18:1n-9)

concentrations but increases palmitate (C16:0), palmitoleate (C16:1n-7), and vaccinate

(C18:1n-7) concentrations (13, 14). We have previously reported that mice with global

deletion of *Elovl6* (GKO) are protected against insulin resistance when fed a high-fat

and high-sucrose (HFHS) diet or when mated to leptin-deficient *ob/ob* mice because the

hepatic FA composition is modified (13). In the present study, we generated

liver-specific *Elovl6* knockout (LKO) mice to investigate the role of Elovl6 in the

hepatic control of lipid metabolism and energy homeostasis.

MATERIALS AND METHODS

Animals.

All animal husbandry and experimental protocols complied with institutional guidelines

10

and were approved by the Animal Experiment Committee of the University of Tsukuba.

The mice were housed in specific pathogen-free conditions under a 12-h light/dark

cycle, with free access to water and either standard chow (MF; Oriental Yeast, Tokyo,

Japan) or a HFHS diet (F2HFHSD; Oriental Yeast, Tokyo, Japan) or a high-sucrose diet

high-sucrose diet (HSD; D11725; Research Diets, New Jersey, USA) in the Laboratory

Animal Resource Center at the University of Tsukuba. The detailed dietary composition

of the HFHS diet and HSD is shown in Supporting Table 1.

Lipidomic profiling.

The MxP® Lipids platform (Metanomics Health GmbH, Berlin, Germany) was used for

the entire lipid analysis workflow as described in the Online Materials and Methods.

Statistical analysis.

Values are expressed as mean ± SEM. Student's t-tests were used to compare the means

of two groups and one-way ANOVA was used for multiple group mean comparisons.

All analyzes were performed using GraphPad Prism 5 (GraphPad Software Inc., CA,

USA), and $p < 0.05$ (two-tailed) was considered to represent statistical significance.

11

RESULTS

LKO mice are not protected from HFHS diet-induced insulin resistance

We generated LKO mice by crossing Elovl6 lox/lox mice with albumin promoter-Cre transgenic mice, which express Cre exclusively in postpartum hepatocytes (Supporting Figure 1). To determine whether liver-specific *Elovl6* deletion produces the same metabolic phenotype as that of GKO mice (13), Flox and LKO mice were fed a normal chow or HFHS diet from 8 weeks of age. There were no differences in body weight (Supporting Figure 2A), liver weights (Supporting Figure 2B), or hepatic TAG or total cholesterol (T-Cho) concentrations (Supporting Figure 2C) between Flox and LKO mice on either a chow or HFHS diet. Epididymal white adipose tissue (eWAT) weight was slightly but significantly lower in LKO mice than in Flox mice on an HFHS diet (Supporting Figure 2B). In contrast to GKO, however, liver-specific Elovl6 deletion did not reduce plasma glucose or insulin concentrations in mice on an HFHS diet (Supporting Figure 2D). Moreover, oral glucose tolerance tests (OGTTs; Supporting Figure 2E) and insulin tolerance tests (ITTs; Supporting Figure 2F) showed no significant differences between Flox and LKO mice fed an HFHS diet. These results

12

demonstrate that hepatocyte-specific *Elovl6* deficiency is insufficient to ameliorate

insulin resistance induced by an HFHS diet.

Insulin sensitivity is higher in LKO mice fed a lipogenic diet

We next fed Flox and LKO mice an HSD for 14 days to induce Elovl6 activity and

DNL, which revealed several phenotypic differences. On the HSD diet, there were no

differences in body, liver and eWAT weights (Supporting Figure 3A), or in plasma lipid

concentrations (Supporting Figure 3B) between Flox and LKO mice. The HSD induced

a similar degree of hepatosteatosis, as demonstrated by increases in hepatic TAG and

T-Cho concentrations (Figure 1A) and number of lipid droplets (LDs) (Supporting

Figure 3C) in both genotypes, compared to the chow diet. Furthermore, *Elovl6* deletion

exacerbated the changes in hepatic FA composition induced by HSD feeding.

Specifically, HSD feeding of LKO mice significantly lowered the stearate and oleate

content, but increased the palmitate, palmitoleate, and vaccinate content, relative to Flox

mice (Figure 1B). HSD-fed LKO mice had significantly lower plasma glucose and

insulin levels compared to HSD-fed Flox controls (Figure 1C). During OGTTs,

HSD-fed LKO mice exhibited lower plasma glucose excursions than HSD-fed Flox

mice, evidenced by a lower area under the curve (AUC; Figure 1D). Furthermore,

13

during ITTs, HSD-fed LKO mice demonstrated lower plasma glucose concentrations than HSD-fed Flox mice (Figure 1E). These results suggest that LKO mice are more insulin-sensitive than Flox mice when consuming an HSD.

We next evaluated insulin signaling following an intravenous injection of insulin. Insulin administration had similar effects on total insulin receptor (IR) and phospho-IR protein levels, and on the ratio of phosphorylated IR to total IR in HSD-fed Flox and LKO mouse liver (Figure 1F). We have previously shown that global *Elovl6* deficiency increases total and phosphorylated insulin receptor substrate (IRS)-2 protein levels and suppresses protein kinase C (PKC) ε activity in the liver, which at least partially explains the amelioration of diet-induced insulin resistance (13). However, the total and phosphorylated levels of IRS-1 and IRS-2 proteins (Supporting Figure 3D), and PKCε translocation to the membrane, an index of PKCε activity (Supporting Figure 3E), were not affected by LKO in the liver of HSD-fed mice. In contrast, the insulin-induced phosphorylation of Akt (Ser473, Thr308) was much higher in the livers of HSD-fed LKO mice than in those of HSD-fed Flox mice (Figure 1F). In addition, the insulin-induced phosphorylation of the Akt substrates glycogen synthase kinase 3 (GSK3) α/β (Ser21/9) and proline-rich Akt substrate of 40 kDa (PRAS40; Thr246) was

significantly higher in the livers of LKO mice than in those of Flox mice. The

insulin-induced phosphorylation of Akt (Ser473) was similar in the eWAT and muscle

of Flox and LKO mice (Supporting Figure 3F). These data demonstrate that the higher

insulin sensitivity in HSD-fed LKO mice is mediated through an enhancement in the

hepatic insulin signaling *via* Akt.

Dietary lipids do not normalize the higher insulin sensitivity in HSD-fed LKO mice

Because stearate and oleate content was lower in the liver of LKO mice, we wished to

determine whether dietary supplementation with these FAs could reverse the increase in

insulin sensitivity identified in HSD-fed LKO mice. We therefore supplemented the

HSD with 20% by mass of both tristearin and triolein. However, after 14 days on a diet

supplemented with stearate and oleate, LKO mice demonstrated greater insulin

sensitivity, as evaluated using an ITT (Supporting Figure 4A), suggesting that FA(s)

endogenously synthesized by Elovl6 are involved in the regulation of hepatic insulin

sensitivity.

LKO mice demonstrate an altered hepatic gene expression profile

To identify candidate genes associated with the enhancement in hepatic insulin

15

sensitivity in HSD-fed LKO mice, livers from Flox and LKO mice fed an HSD were

profiled using microarray analysis. The heatmap in Figure 2A and Supporting Table 2

list all the genes with significant differences in expression *versus* controls. Pathway

analysis revealed highly significant downregulation of eight pathways involved in lipid

metabolism (Figure 2B). We next performed quantitative real-time PCR (qPCR)

analysis to confirm the major findings of the microarray analysis, and found that

liver-specific Elovl6 deficiency was associated with lower expression of sterol

regulatory element binding protein 1c (*Srebf1c*) mRNA (Figure 2C) and the nuclear

active form of SREBP-1 protein (Supporting Figure 4B), the major transcription factor

involved in the transcriptional regulation of lipogenesis by carbohydrates (8, 15).

Moreover, liver-specific Elovl6 deficiency significantly impaired the HSD-induced

upregulation of hepatic mRNAs encoding lipogenic enzymes, such as acetyl-CoA

carboxylase 1 (*Acc1*), fatty acid synthase (*Fasn*), and stearoyl-CoA desaturase 1 (*Scd1*)

(Supporting Figure 4C). A volcano plot demonstrates that the genes significantly

downregulated by *Elovl6* deficiency (Supporting Figure 4D) included patatin-like

phospholipase domain containing 3 (*Pnpla3*), which encodes a membrane-bound

protein with a predominant TAG lipase activity (16, 17). qPCR analysis confirmed that

Pnpla3 expression was increased 67-fold by HSD feeding in the liver of Flox mice and

16

reduced by 68% in the liver of LKO mice (Figure 2C). A similar expression pattern was

also identified for the *Pnpla3* paralog *Pnpla5* (Supporting Figure 4E). In addition, we

performed immunoblotting for Pnpla3 and found that its protein abundance was lower

in the liver of LKO mice than in that of Flox mice (Supporting Figure 4F).

Downregulation of Pnpla3 mediates the increase in insulin sensitivity in HSD-fed

LKO mice

To determine if the Pnpla3 reduction contributes to the higher insulin sensitivity in

HSD-fed LKO mice, Flox and LKO mice consuming an HSD were injected with a

recombinant adenovirus encoding mouse Pnpla3 (Ad-Pnpla3) or green fluorescent

protein (Ad-GFP). Hepatic Pnpla3 protein was expressed at similar levels in HSD-fed

Ad-Pnpla3-infected LKO mice and Flox mice, according to the results of

immunoblotting (Figure 2D). Pnpla3 overexpression did not affect body weight, but

increased liver weight to a similar extent in both Flox and LKO mice (Supporting

Figure 5A). However, Pnpla3 overexpression did not affect the hepatic lipid content

(Supporting Figure 5B, C) or liver pathology (Supporting Figure 5C, D) in Flox and

LKO mice. Remarkably, the restoration of hepatic Pnpla3 protein expression in

HSD-fed LKO mice reversed both the increase in insulin sensitivity (Figure 2E) and the

increase in the insulin-stimulated phosphorylation of hepatic Akt (Ser473, Thr308), GSK3α/β, and PRAS40 (Figure 2F). These results suggest that Elovl6- and Pnpla3-dependent lipid metabolic pathways are crucial in the regulation of hepatic insulin signaling under lipogenic conditions.

Lipid profiling of Elovl6- and Pnpla3-regulated lipids in the liver

We hypothesized that Elovl6 and Pnpla3 cooperate in the regulation of hepatic insulin sensitivity by changing the acyl-chain composition of specific lipid(s) that modulate insulin action. To test this hypothesis, we performed lipidomics on liver samples from HSD-fed Flox and LKO mice injected with either Ad-GFP or Ad-Pnpla3. Deletion of *Elov6* significantly increased the content of 39 lipid metabolites and reduced the content of 39 other lipid metabolites in the liver (Figure 3A and Supporting Table 3). These Elovl6-related changes occurred in a variety of lipids, including ceramides, cholesterol esters, FFAs, phospholipids (PLs), lysoPL, sphingomyelins, and TAG. Conversely, the restoration of hepatic Pnpla3 expression in LKO mice increased the content of six lipid metabolites and reduced the content of 27 metabolites in the liver (Figure 3A and Supporting Table 3). Consistent with a physiologic role of Pnpla3 in determining the TAG and PL composition of hepatic LDs (18-20), Pnpla3 expression altered the

18

distribution of TAG and FFA species, as well as of ceramide and sphingomyelin

species. Among these, the following specific lipids exhibited changes corresponding to

the effects of manipulating Elovl6 and Pnpla3. The concentration of

ceramide(d18:1/18:0) was lower in LKO liver than in Flox liver and was increased by

the restoration of Pnpla3 expression in LKO mice. In contrast, the concentration of

ceramide(d18:2/22:1) was higher in LKO liver than in Flox liver, and was reduced by

the restoration of Pnpla3 expression.

Ceramides have been implicated in the lipid-induced inhibition of insulin sensitivity

(21-23). Moreover, specific ceramide species, which are defined by their fatty

acyl-chain length, can have specific biologic functions (24-26). Therefore, we expanded

our initial lipidomic analysis by analyzing multiple ceramide species to determine

whether their hepatic concentrations are modulated by Elovl6 and Pnpla3. The total

hepatic ceramide content was not significantly affected by genotype, diet, or adenovirus

infection (Supporting Figure 6A), and 19 of the ceramide species evaluated were similar

in abundance between the HSD-fed Flox and LKO mice (Figure 3B). However, Elovl6

deficiency significantly reduced the content of ceramide(d18:1/18:0) and

ceramide(d18:2/18:0) in the liver. In contrast, restoration of Pnpla3 significantly

increased the content of ceramide(d18:1/18:0) and ceramide(d18:1/20:0), but significantly reduced the content of ceramide(d18:2/22:1) in the liver of HSD-fed LKO mice (Figure 3C). An injection of a small quantity of Pnpla3 adenovirus significantly increased the content of ceramide(d18:1/16:0) and ceramide(d18:1/18:0), and significantly reduced the content of ceramide(d18:2/22:1) in the liver of HSD-fed Flox mice. Elovl6 deficiency significantly reduced the HSD-induced increase in hepatic ceramide(d18:1/18:0), and this effect was attenuated by the restoration of Pnpla3 expression (Figure 3B, C). Thus, changes in ceramide(d18:1/18:0) concentration are strongly associated with the insulin sensitivity of LKO mice.

Ceramide(d18:1/18:0) increases PP2A activity and inhibits insulin signaling by reducing the interaction between PP2A and I2PP2A

Because ceramides are known to regulate insulin sensitivity by activating PP2A and PKCζ (21-23), we assessed the hepatic activities of PP2A and PKCζ. HSD-feeding significantly increased PP2A activity in the liver of Flox mice, but not LKO mice (Figure 3D). The restoration of hepatic Pnpla3 expression in HSD-fed LKO mice significantly increased PP2A activity to a level comparable to that of HSD-fed Flox mice (Figure 3D). We also assessed the phosphorylation status of hepatic PKCζ and

20

found that phosphorylation at Thr410, which is required for PKCζ activation (21), was

not altered by Elovl6 deficiency or HSD-feeding (Figure 3E). These results suggest that

the higher hepatic insulin sensitivity in HSD-fed LKO mice may be mediated through

the suppression of C18:0-ceramide production, resulting in a reduction in

ceramide-induced PP2A activity in the liver and lower PP2A-dependent downregulation

of insulin signaling, implying a disinhibition of insulin signaling.

To determine whether ceramide(d18:1/18:0) inhibits insulin signaling, human hepatoma

HepG2 cells were treated with 10 μM ceramide(d18:1/16:0), ceramide(d18:1/18:0), or

ceramide(d18:1/20:0) for 4 h, and with vehicle or insulin for the last 10 min of this

period (Figure 4A). Treatment with ceramide(d18:1/16:0) or ceramide(d18:1/20:0) did

not affect insulin-stimulated phosphorylation of Akt, but ceramide(d18:1/18:0)

treatment significantly suppressed the insulin-stimulated phosphorylation of Akt

compared to vehicle and ceramide(d18:1/16:0) treatment.

Ceramide inhibits insulin signaling by activating PP2A, a serine/threonine phosphatase

that dephosphorylates and thus deactivates Akt (27). Previous studies have

demonstrated that PP2A activity is modulated by phosphorylation at Tyr307 and

carboxymethylation at Leu309 of the C subunit (28). Immunoblot analysis revealed that

Elovl6 deficiency and Pnpla3 expression did not affect the levels of phosphorylation or

carboxymethylation of the PP2A C subunit in the liver (Supporting Figure 6B). In

addition, ceramide activates PP2A activity in part via direct binding of Inhibitor 2 of

PP2A (I2PP2A/SET oncogene), which prevents the interaction between PP2A and

I2PP2A (27, 29). Notably, I2PP2A preferentially binds C18-ceramides over C14–C16

ceramides (30, 31). We hypothesized that if the major effect of Elovl6 deficiency on

hepatic insulin signaling is to reduce hepatic ceramide(d18:1/18:0) production, this

effect would be modulated by altering I2PP2A–PP2A binding. To test this hypothesis,

HepG2 cells transfected with HA-tagged PP2A catalytic subunit alpha isoform

(PPP2CA) and FLAG-tagged I2PP2A were treated with ceramide(d18:1/16:0),

ceramide(d18:1/18:0), or ceramide(d18:1/20:0). Ceramide(d18:1/16:0) did not change

the PPP2CA–I2PP2A interaction, but ceramide(d18:1/18:0) and ceramide(d18:1/20:0)

significantly inhibited the PPP2CA–I2PP2A interaction (Figure 4B). This reduction in

the PPP2CA–I2PP2A interaction was much larger in ceramide(d18:1/18:0)-treated cells

than in ceramide(d18:1/20:0)-treated cells.

To confirm the role of I2PP2A in ceramide(d18:1/18:0)-induced insulin resistance,

22

HepG2 cells were infected with lentivirus expressing a short hairpin RNA (shRNA) targeting I2PP2A or a scrambled shRNA (control). Immunoblotting confirmed a significant reduction in the abundance of I2PP2A protein following infection with the specific shRNA (Figure 4C). In HepG2 cells infected with control shRNA, ceramide(d18:1/18:0) reduced the insulin-stimulated phosphorylation of Akt (Figure 4C). Knockdown of I2PP2A reduced the insulin-stimulated phosphorylation of Akt and abrogated the inhibitory effect of ceramide(d18:1/18:0) on the insulin-stimulated phosphorylation of Akt (Figure 4C). Thus, ceramide(d18:1/18:0) inhibits Akt signaling in a I2PP2A-dependent manner to regulate PP2A activity.

To determine the structural basis of the interaction between ceramides and I2PP2A, we performed molecular modeling using the crystal structure of I2PP2A and ceramide(d18:1/16:0), ceramide(d18:1/18:0), or ceramide(d18:1/20:0) as probes, and studied their interactions quantitatively using the first-principles calculations-based fragment molecular orbital method (32). The relative binding scores, the theoretical interaction energies between each ceramide and I2PP2A, from the value of ceramide(d18:1/16:0), are shown in Figure 4D. Consistent with the biologic data, this model suggested that the binding affinity of each species to I2PP2A is in the descending

23

order ceramide(d18:1/18:0), ceramide(d18:1/20:0), and ceramide(d18:1/16:0). Thus, the

potent effect of ceramide(d18:1/18:0) on I2PP2A–PP2A binding shown by *in vivo* and

in vitro assays was also confirmed by a computer simulation.

Ceramide synthase (CerS) associates with Elovl6 and Pnpla3 on the endoplasmic

reticulum (ER) and at the ER-LD interface, respectively

Our findings suggest that both Elovl6 and Pnpla3 are involved in metabolic pathways

that regulating ceramide acyl species. *De novo* ceramide synthesis involves six distinct

CerSs, CerS1 to CerS6, which are specialized for the synthesis of ceramides with

different fatty acyl-chain lengths (26). Therefore, we sought to identify physical

interactions among Elovl6, Pnpla3, and CerS4, a CerS that synthesizes C18–C20

ceramides and is highly expressed in the liver (33).

We first characterized the subcellular distributions of each protein in HEK293 cells

using confocal microscopy. When expressed in HEK293 cells treated with oleate to

increase LD formation, C-terminal FLAG-tagged Elovl6 (Elovl6-FLAG) and V5-tagged

CerS4 (CerS4-V5) displayed a reticular distribution that likely corresponded to the ER

(Supporting Figure 7A). Consistent with previous reports, HA-tagged Pnpla3

24

(Pnpla3-HA) accumulated on membranes and in LDs (Supporting Figure 7B). In

co-expression experiments, Elovl6-FLAG appeared to colocalize with CerS4-V5 in the

ER, while Pnpla3-HA and CerS4-V5 appeared to colocalize at the ER-LD interface

upon oleate loading (Figure 5A). When co-expressed with Elovl6-FLAG, Pnpla3-HA

displayed a reticular distribution, likely corresponding to the ER and LDs (Figure 5A).

However, within 24 h of transfection, both Elovl6-FLAG- and Pnpla3-HA-expressing

HEK293 cells were smaller and rounder, with dense cytoplasm and tightly-packed

organelles, suggestive of the induction of apoptosis, which was presumably due to the

greater production of C18:0-ceramide and the higher PP2A activity (27).

We next aimed to identify interactions among Elovl6, Pnpla3, and CerS4 by

immunoprecipitation from co-overexpressing cells. HEK293 cells were transfected with

Elovl6-FLAG and CerS4-V5, Pnpla3-HA and CerS4-V5, or Elovl6-FLAG and

Pnpla3-HA, and then treated with oleate for 24 h. This confirmed the interaction of

Elovl6-FLAG with CerS4-V5 (Figure 5B and Supporting Figure 8A), and Pnpla3-HA

was also shown to interact with CerS4-V5 (Figure 5B and Supporting Figure 8B).

However, Elovl6-FLAG did not interact with Pnpla3-HA (Figure 5B and Supporting

Figure 8C). Taken together, these results suggest that Elovl6 and Pnpla3 may be

25

involved in regulating a pool of C18:0-ceramide by forming Elovl6-CerS4 and

Pnpla3-CerS4 complexes on the ER and at the ER-LD interface, respectively.

Liver-specific deletion of *Elovl6* ameliorates insulin resistance in *ob/ob* mice

To further define the role of hepatic Elovl6 in obesity and insulin resistance, we

assessed the effects of liver-specific *Elovl6* deletion in leptin-deficient *ob/ob* mice, a

widely used animal model of severe obesity, steatohepatitis, and insulin resistance.

Mice with liver-specific disruption of Elovl6 (*ob/ob*-LKO) were severely obese, with

similar body and eWAT weight to those of *ob/ob* mice (Figure 6A). Liver weight was

significantly greater in *ob/ob*-LKO mice than in *ob/ob* mice (Figure 6A), but with

similar degrees of hepatosteatosis (Supporting Figure 9A–C), although there were

prominent differences in FA composition (Supporting Figure 9D). Liver-specific

disruption of *Elovl6* significantly reduced plasma glucose and insulin concentrations

compared to *ob/ob* mice (Figure 6B). OGTTs showed that glucose intolerance was

moderately ameliorated in *ob/ob*-LKO mice *versus* *ob/ob* mice (Figure 6C).

Furthermore, ITTs showed that the insulin resistance was significantly less severe in

ob/ob-LKO mice than in *ob/ob* mice (Figure 6C). The expression of lipogenic genes,

including *Elovl6*, *Srebf1c*, *Fasn*, *Scd1*, and *Pnpla3*, was significantly higher in the livers

26

of *ob/ob* mice than in Flox mice (Figure 6D). However, *ob/ob*-LKO mice showed

significantly lower hepatic expression of these lipogenic genes than *ob/ob* mice. We

also quantified the relative content of representative ceramide species in the livers of

Flox, *ob/ob*, and *ob/ob*-LKO mice and found that the increase in ceramide(d18:1/18:0)

content in *ob/ob* mouse liver was absent in *ob/ob*-LKO mouse liver (Figure 6E).

Moreover, the content of hepatic ceramide(d18:1/20:0), ceramide(d18:1/24:1),

ceramide(d17:1/18:0), ceramide(d17:1/24:1), ceramide(d18:2/18:0), and

ceramide(d18:2/20:0) was significantly lower, and the content of ceramide(d18:1/16:0)

was significantly higher in *ob/ob*-LKO mice than in *ob/ob* mice. The activity of PP2A

in the liver of *ob/ob*-LKO mice was also lower than in *ob/ob* mice (Figure 6F), which

was comparable to the trend identified in Flox mice. Taking these results together, it can

be concluded that hepatic Elovl6-mediated C18:0-ceramide production regulates insulin

sensitivity through the modulation of PP2A activity under lipogenic conditions, and that

liver-specific deletion of Elovl6 can ameliorate insulin resistance in the obese diabetic

state.

DISCUSSION

27

In the present study, we aimed to determine the role of hepatic Elovl6-synthesized long-chain FAs in lipid metabolism and glucose homeostasis by generating liver-specific *Elovl6*-deficient mice. Our results demonstrate that hepatic Elovl6 regulates hepatic insulin sensitivity, in part by affecting the hepatic ceramide FA composition. In turn, ceramide FA composition regulates insulin signaling under lipogenic conditions by modulating the interaction between I2PP2A and PP2A, and PP2A activity. The proposed pathway is presented in Figure 7 and Supporting Figure 9E.

There is increasing evidence that diets high in carbohydrate result in greater DNL, obesity, ectopic lipid accumulation, and insulin resistance in animals, as well as in humans (23, 34–36). Hyperglycemia stimulates pancreatic insulin secretion, which, together with dietary carbohydrate, stimulates hepatic DNL by upregulating lipogenic gene transcription. The transcription factors responsible for mediating this include SREBP-1c, which regulates hepatic DNL primarily by regulating the expression of genes involved in DNL, lipid homeostasis, and glucose metabolism (8). *Elovl6* expression is highly responsive to carbohydrates and insulin, and its promoter contains

28

response elements for SREBP-1c (12, 37). *Pnpla3* expression is also strongly induced

by carbohydrate feeding and insulin through the lipogenic transcription factors

SREBP-1c and carbohydrate-response element-binding protein (38, 39). Moreover,

accumulation of long-chain FAs, such as stearate and oleate, the major end-products of

the SREBP-1c pathway, prevents the degradation of the Pnpla3 protein by the

proteasome and stabilize it, thereby increasing its abundance (38). We found that the

expression levels of *Srebf1c* and its target lipogenic genes, including *Acc1*, *Fasn*, *Scd1*,

and *Pnpla3*, were collectively suppressed in the livers of HSD-fed LKO mice. How

does hepatic Elovl6 regulate lipogenic gene expression? On an HSD diet, hepatic Elovl6

deficiency markedly reduced the nuclear levels of SREBP-1, indicating that hepatic

Elovl6 expression and its products are required for the maturation and nuclear

translocation of active SREBP-1 protein. Although the mechanism whereby Elovl6

deficiency reduces the maturation of SREBP-1 protein and *Srebf1c* mRNA expression

remains to be elucidated, a recent study has suggested that the altered acyl-chain

composition of PLs in the ER induced by Elovl6 deficiency may reduce SREBP-1

post-translational processing (40).

Our data demonstrate a novel role for hepatic Elovl6 in the regulation of insulin

29

signaling. Elovl6 is linked to the generation of ceramide species that activate PP2A by disrupting interactions with its endogenous inhibitor I2PP2A. Ceramides are bioactive sphingolipids, mainly composed of a sphingosine backbone and FA chains of variable length and saturation (26, 41). Several studies have indicated indicate that specific ceramide species possess distinct physiologic activities (24, 25, 42). In particular, C16:0-ceramide appears to have a critical role in the pathophysiology of insulin resistance. For example, mice with global or liver-specific *CerS6* knockout exhibit a lower C16:0-ceramide concentration and are protected against diet-induced obesity, insulin resistance, and adipose tissue inflammation (25). A complementary paper found that heterozygous *CerS2* knockout mice exhibit high C16:0-ceramide concentrations, hepatosteatosis, glucose intolerance, and insulin resistance (24). The present findings suggest that hepatic Elovl6 deficiency increases insulin sensitivity by reducing C18:0-ceramide concentration, which maintains the inhibition of PP2A by I2PP2A, thereby increasing Akt activity, a key insulin signaling intermediate. Consistent with this notion, an important role of ceramide(d18:1/18:0) in the development of insulin resistance has been demonstrated in several studies. In mice, increasing acid ceramidase expression in the liver reduces the concentrations of C16:0- and C18:0-ceramides and improves insulin action, implying that these ceramide species may inhibit insulin

signaling (42). Luukkonen et al. have recently reported that ceramide(d18:1/18:0) is among the species that are present in significantly higher concentrations in the livers of patients with high homeostasis model assessment-insulin resistance, and are most strongly associated with insulin resistance (43). Moreover, studies in humans have shown that plasma ceramide(d18:1/18:0) concentration is significantly higher and is strongly associated with T2D and prediabetes (44, 45). Overall, these results strongly suggest that C18:0-ceramide suppresses insulin sensitivity. We believe that the present findings regarding Elovl6 contribute to understanding the molecular mechanisms that mediate these associations.

Hepatic Pnpla3 is expressed predominantly in hepatocytes, in which it is found on the ER and LD membrane (38, 46). *In vitro* studies have demonstrated that purified recombinant human PNPLA3 catalyzes the hydrolysis of the three major glycerolipids, TAGs, diacylglycerols, and monoacylglycerols, but is most effective with respect to TAGs (38, 47, 48). A recent *in vitro* study also suggested that Pnpla3 alters the TAG and PL composition of LDs by catalyzing the transfer of very long-chain PUFAs from TAGs to PLs (20). The present results suggest that Pnpla3 is involved in the synthesis of ceramides *in vivo*.

31

In addition to the ER, our results identify the ER-LD interface as a source of ceramides, and C18:0-ceramide generation is mainly catalyzed by CerS4 in the liver (26, 33). The co-overexpression of Pnpla3 and CerS4 in HEK293 cells suggested that Pnpla3 modifies ceramide FA composition by forming an enzyme complex with CerS4 at the ER-LD interface. Consistent with this result, Senkal *et al*. recently reported that CerSs localize to LDs and form a multi-enzyme complex with acyl-CoA synthetase long-chain family member 5 and diacylglycerol O-acyltransferase 2 at the ER-LD interface, where they generate acylceramides from ceramides and fatty acyl-CoAs (49). Therefore, it is possible that the regulation of ceramide species by Pnpla3 may be facilitated by the release of FAs from hepatic LDs. Pnpla3 is a TAG hydrolase that acts at the surface of LDs, where it releases FAs from TAGs, making them available for incorporation into ceramides. This possibility is supported by a lipidomic study of *ob/ob* mice showing an association between greater deposition of TAG species in the liver and a proportional increase in hepatic ceramide(d18:1/18:0) content (50).

Overall, the results of the present study demonstrate that liver-specific deletion of Elovl6 enhances insulin sensitivity in mice by reducing the generation of ceramides

involved in the endogenous activation of PP2A. Although we cannot rule out the possibility that Elovl6 deficiency affects the acyl-chain composition of other lipids that regulate hepatic insulin sensitivity given that our lipidomic platform did not determine the fatty acyl constituents, positional isomers, or double bond positions in the lipid fractions containing PLs, TAGs, and diacylglycerols, the present results strongly suggest that C18:0-ceramide is important in the regulation of insulin sensitivity in lipogenic conditions. Our observations linking Elovl6 and ceramides could thus provide new insight into the pathophysiology of insulin resistance and suggest that inhibition of Elovl6 may represent a therapeutic target for the amelioration of insulin resistance.

Figure 7. Schematic description of the Elovl6/Pnpla3/CerS pathway regulating

hepatic insulin signaling

Excess consumption of carbohydrate and hyperinsulinemia activate *de novo* lipogenesis

and upregulate the expression of Elovl6 and Pnpla3 in the liver. Activation of Elovl6

increases the amount of C18:0, enhancing C18:0-ceramide production through

formation of an enzyme complex with CerS4 on the ER. Pnpla3 acts on the surface of

LDs, releases FAs from TAGs, and modifies ceramide FA composition by forming an

enzyme complex with CerS4 at the ER-LD interface. Both Elovl6 and Pnpla3 are linked

47

to the generation of C18:0-ceramide, which activates PP2A by disrupting the

interactions with its endogenous inhibitor I2PP2A. As a consequence, PP2A inhibits

insulin signaling by impairing Akt activation.

ABSTRACT

Dysfunctional hepatic lipid metabolism is a cause of non-alcoholic fatty liver disease (NAFLD), the most common chronic liver disorder worldwide, and is closely associated with insulin resistance and type 2 diabetes (T2D). ELOVL fatty acid elongase 6 (Elovl6) is responsible for converting C16 saturated and monounsaturated fatty acids (FAs) into C18 species. We have previously shown that Elovl6 contributes to obesity-induced insulin resistance by modifying hepatic C16/C18-related FA composition. To define the precise molecular mechanism by which hepatic Elovl6 affects energy homeostasis and metabolic disease, we generated liver-specific Elovl6 knockout (LKO) mice. Unexpectedly, LKO mice were not protected from high-fat diet-induced insulin resistance. Instead, LKO mice exhibited higher insulin sensitivity than controls when consuming a high-sucrose diet (HSD), which induces lipogenesis. Hepatic patatin-like phospholipase domain-containing protein 3 (Pnpla3) expression was downregulated in LKO mice, and adenoviral Pnpla3 restoration reversed the enhancement in insulin sensitivity in HSD-fed LKO mice. Lipidomic analyzes showed that the hepatic ceramide(d18:1/18:0) content was lower in LKO mice, which may explain the effect on insulin sensitivity. Ceramide(d18:1/18:0) enhances protein

7

phosphatase 2A (PP2A) activity by interfering with the binding of PP2A to its

biological inhibitor I2PP2A, leading to Akt dephosphorylation. Its production involves

the formation of an Elovl6-ceramide synthase 4 (CerS4) complex in the endoplasmic

reticulum (ER) and a Pnpla3-CerS4 complex on lipid droplets (LDs). Consistent with

this, liver-specific Elovl6 deletion in ob/ob mice reduced both hepatic

ceramide(d18:1/18:0) and PP2A activity, and ameliorated insulin resistance.

Conclusion: Our study demonstrates the key role of hepatic Elovl6 in the regulation of

the acyl-chain composition of ceramide, and that C18:0-ceramide is a potent regulator

of hepatic insulin signaling linked to Pnpla3-mediated NAFLD.

8

INTRODUCTION

Non-alcoholic fatty liver disease (NAFLD), characterized by excessive triacylglycerol (TAG) accumulation in hepatocytes, is recognized as a hepatic phenotype of the metabolic syndrome (1). A large majority of obese and diabetic individuals develop NAFLD, but it is also a risk factor for various other conditions, including insulin resistance, hyperlipidemia, and type 2 diabetes (T2D) (2, 3). Furthermore, non-alcoholic steatohepatitis (NASH), a severe form of NAFLD characterized by hepatocellular damage, lobular inflammation, abnormal glucose tolerance, and fibrosis, can progress to cirrhosis and hepatocellular carcinoma (4, 5).

Chronic and/or excess consumption of carbohydrates and saturated fatty acids (FAs) is associated with the development of hepatic insulin resistance (6, 7). Hepatic insulin resistance promotes aberrant glucose production, *de novo* lipogenesis (DNL), atherogenic dyslipidemia, and NAFLD, which are major risk factors for T2D and cardiovascular disease (8, 9). There are few effective therapies for hepatic insulin resistance or obesity, and the development of novel therapeutics necessitates a better understanding of the mechanistic relationship between obesity and NAFLD.

9

Elongation and desaturation are central steps in the *de novo* synthesis of long-chain

FAs, and length and saturation are critical determinants of FA function and metabolic

fate (10). ELOVL fatty acid elongase 6 (Elovl6) is a microsomal enzyme that is

involved in the elongation of C16 saturated and monounsaturated FAs to form C18 FAs

(11, 12). Loss of Elovl6 function reduces stearate (C18:0) and oleate (C18:1n-9)

concentrations but increases palmitate (C16:0), palmitoleate (C16:1n-7), and vaccinate

(C18:1n-7) concentrations (13, 14). We have previously reported that mice with global

deletion of *Elovl6* (GKO) are protected against insulin resistance when fed a high-fat

and high-sucrose (HFHS) diet or when mated to leptin-deficient *ob/ob* mice because the

hepatic FA composition is modified (13). In the present study, we generated

liver-specific *Elovl6* knockout (LKO) mice to investigate the role of Elovl6 in the

hepatic control of lipid metabolism and energy homeostasis.

MATERIALS AND METHODS

Animals.

All animal husbandry and experimental protocols complied with institutional guidelines

10

and were approved by the Animal Experiment Committee of the University of Tsukuba.

The mice were housed in specific pathogen-free conditions under a 12-h light/dark

cycle, with free access to water and either standard chow (MF; Oriental Yeast, Tokyo,

Japan) or a HFHS diet (F2HFHSD; Oriental Yeast, Tokyo, Japan) or a high-sucrose diet

high-sucrose diet (HSD; D11725; Research Diets, New Jersey, USA) in the Laboratory

Animal Resource Center at the University of Tsukuba. The detailed dietary composition

of the HFHS diet and HSD is shown in Supporting Table 1.

Lipidomic profiling.

The MxP® Lipids platform (Metanomics Health GmbH, Berlin, Germany) was used for

the entire lipid analysis workflow as described in the Online Materials and Methods.

Statistical analysis.

Values are expressed as mean ± SEM. Student's t-tests were used to compare the means

of two groups and one-way ANOVA was used for multiple group mean comparisons.

All analyzes were performed using GraphPad Prism 5 (GraphPad Software Inc., CA,

USA), and $p < 0.05$ (two-tailed) was considered to represent statistical significance.

11

RESULTS

LKO mice are not protected from HFHS diet-induced insulin resistance

We generated LKO mice by crossing Elovl6 lox/lox mice with albumin promoter-Cre

transgenic mice, which express Cre exclusively in postpartum hepatocytes (Supporting

Figure 1). To determine whether liver-specific *Elovl6* deletion produces the same

metabolic phenotype as that of GKO mice (13), Flox and LKO mice were fed a normal

chow or HFHS diet from 8 weeks of age. There were no differences in body weight

(Supporting Figure 2A), liver weights (Supporting Figure 2B), or hepatic TAG or total

cholesterol (T-Cho) concentrations (Supporting Figure 2C) between Flox and LKO

mice on either a chow or HFHS diet. Epididymal white adipose tissue (eWAT) weight

was slightly but significantly lower in LKO mice than in Flox mice on an HFHS diet

(Supporting Figure 2B). In contrast to GKO, however, liver-specific Elovl6 deletion did

not reduce plasma glucose or insulin concentrations in mice on an HFHS diet

(Supporting Figure 2D). Moreover, oral glucose tolerance tests (OGTTs; Supporting

Figure 2E) and insulin tolerance tests (ITTs; Supporting Figure 2F) showed no

significant differences between Flox and LKO mice fed an HFHS diet. These results

12

demonstrate that hepatocyte-specific *Elovl6* deficiency is insufficient to ameliorate

insulin resistance induced by an HFHS diet.

Insulin sensitivity is higher in LKO mice fed a lipogenic diet

We next fed Flox and LKO mice an HSD for 14 days to induce Elovl6 activity and

DNL, which revealed several phenotypic differences. On the HSD diet, there were no

differences in body, liver and eWAT weights (Supporting Figure 3A), or in plasma lipid

concentrations (Supporting Figure 3B) between Flox and LKO mice. The HSD induced

a similar degree of hepatosteatosis, as demonstrated by increases in hepatic TAG and

T-Cho concentrations (Figure 1A) and number of lipid droplets (LDs) (Supporting

Figure 3C) in both genotypes, compared to the chow diet. Furthermore, *Elovl6* deletion

exacerbated the changes in hepatic FA composition induced by HSD feeding.

Specifically, HSD feeding of LKO mice significantly lowered the stearate and oleate

content, but increased the palmitate, palmitoleate, and vaccinate content, relative to Flox

mice (Figure 1B). HSD-fed LKO mice had significantly lower plasma glucose and

insulin levels compared to HSD-fed Flox controls (Figure 1C). During OGTTs,

HSD-fed LKO mice exhibited lower plasma glucose excursions than HSD-fed Flox

mice, evidenced by a lower area under the curve (AUC; Figure 1D). Furthermore,

13

during ITTs, HSD-fed LKO mice demonstrated lower plasma glucose concentrations

than HSD-fed Flox mice (Figure 1E). These results suggest that LKO mice are more

insulin-sensitive than Flox mice when consuming an HSD.

We next evaluated insulin signaling following an intravenous injection of insulin.

Insulin administration had similar effects on total insulin receptor (IR) and phospho-IR

protein levels, and on the ratio of phosphorylated IR to total IR in HSD-fed Flox and

LKO mouse liver (Figure 1F). We have previously shown that global *Elovl6* deficiency

increases total and phosphorylated insulin receptor substrate (IRS)-2 protein levels and

suppresses protein kinase C (PKC) ε activity in the liver, which at least partially

explains the amelioration of diet-induced insulin resistance (13). However, the total and

phosphorylated levels of IRS-1 and IRS-2 proteins (Supporting Figure 3D), and PKCε

translocation to the membrane, an index of PKCε activity (Supporting Figure 3E), were

not affected by LKO in the liver of HSD-fed mice. In contrast, the insulin-induced

phosphorylation of Akt (Ser473, Thr308) was much higher in the livers of HSD-fed

LKO mice than in those of HSD-fed Flox mice (Figure 1F). In addition, the

insulin-induced phosphorylation of the Akt substrates glycogen synthase kinase 3

(GSK3) α/β (Ser21/9) and proline-rich Akt substrate of 40 kDa (PRAS40; Thr246) was

14

significantly higher in the livers of LKO mice than in those of Flox mice. The

insulin-induced phosphorylation of Akt (Ser473) was similar in the eWAT and muscle

of Flox and LKO mice (Supporting Figure 3F). These data demonstrate that the higher

insulin sensitivity in HSD-fed LKO mice is mediated through an enhancement in the

hepatic insulin signaling *via* Akt.

Dietary lipids do not normalize the higher insulin sensitivity in HSD-fed LKO mice

Because stearate and oleate content was lower in the liver of LKO mice, we wished to

determine whether dietary supplementation with these FAs could reverse the increase in

insulin sensitivity identified in HSD-fed LKO mice. We therefore supplemented the

HSD with 20% by mass of both tristearin and triolein. However, after 14 days on a diet

supplemented with stearate and oleate, LKO mice demonstrated greater insulin

sensitivity, as evaluated using an ITT (Supporting Figure 4A), suggesting that FA(s)

endogenously synthesized by Elovl6 are involved in the regulation of hepatic insulin

sensitivity.

LKO mice demonstrate an altered hepatic gene expression profile

To identify candidate genes associated with the enhancement in hepatic insulin

15

sensitivity in HSD-fed LKO mice, livers from Flox and LKO mice fed an HSD were profiled using microarray analysis. The heatmap in Figure 2A and Supporting Table 2 list all the genes with significant differences in expression *versus* controls. Pathway analysis revealed highly significant downregulation of eight pathways involved in lipid metabolism (Figure 2B). We next performed quantitative real-time PCR (qPCR) analysis to confirm the major findings of the microarray analysis, and found that liver-specific Elovl6 deficiency was associated with lower expression of sterol regulatory element binding protein 1c (*Srebf1c*) mRNA (Figure 2C) and the nuclear active form of SREBP-1 protein (Supporting Figure 4B), the major transcription factor involved in the transcriptional regulation of lipogenesis by carbohydrates (8, 15). Moreover, liver-specific Elovl6 deficiency significantly impaired the HSD-induced upregulation of hepatic mRNAs encoding lipogenic enzymes, such as acetyl-CoA carboxylase 1 (*Acc1*), fatty acid synthase (*Fasn*), and stearoyl-CoA desaturase 1 (*Scd1*) (Supporting Figure 4C). A volcano plot demonstrates that the genes significantly downregulated by *Elovl6* deficiency (Supporting Figure 4D) included patatin-like phospholipase domain containing 3 (*Pnpla3*), which encodes a membrane-bound protein with a predominant TAG lipase activity (16, 17). qPCR analysis confirmed that *Pnpla3* expression was increased 67-fold by HSD feeding in the liver of Flox mice and

16

reduced by 68% in the liver of LKO mice (Figure 2C). A similar expression pattern was

also identified for the *Pnpla3* paralog *Pnpla5* (Supporting Figure 4E). In addition, we

performed immunoblotting for Pnpla3 and found that its protein abundance was lower

in the liver of LKO mice than in that of Flox mice (Supporting Figure 4F).

Downregulation of Pnpla3 mediates the increase in insulin sensitivity in HSD-fed

LKO mice

To determine if the Pnpla3 reduction contributes to the higher insulin sensitivity in

HSD-fed LKO mice, Flox and LKO mice consuming an HSD were injected with a

recombinant adenovirus encoding mouse Pnpla3 (Ad-Pnpla3) or green fluorescent

protein (Ad-GFP). Hepatic Pnpla3 protein was expressed at similar levels in HSD-fed

Ad-Pnpla3-infected LKO mice and Flox mice, according to the results of

immunoblotting (Figure 2D). Pnpla3 overexpression did not affect body weight, but

increased liver weight to a similar extent in both Flox and LKO mice (Supporting

Figure 5A). However, Pnpla3 overexpression did not affect the hepatic lipid content

(Supporting Figure 5B, C) or liver pathology (Supporting Figure 5C, D) in Flox and

LKO mice. Remarkably, the restoration of hepatic Pnpla3 protein expression in

HSD-fed LKO mice reversed both the increase in insulin sensitivity (Figure 2E) and the

17

increase in the insulin-stimulated phosphorylation of hepatic Akt (Ser473, Thr308), GSK3α/β, and PRAS40 (Figure 2F). These results suggest that Elovl6- and Pnpla3-dependent lipid metabolic pathways are crucial in the regulation of hepatic insulin signaling under lipogenic conditions.

Lipid profiling of Elovl6- and Pnpla3-regulated lipids in the liver

We hypothesized that Elovl6 and Pnpla3 cooperate in the regulation of hepatic insulin sensitivity by changing the acyl-chain composition of specific lipid(s) that modulate insulin action. To test this hypothesis, we performed lipidomics on liver samples from HSD-fed Flox and LKO mice injected with either Ad-GFP or Ad-Pnpla3. Deletion of *Elov6* significantly increased the content of 39 lipid metabolites and reduced the content of 39 other lipid metabolites in the liver (Figure 3A and Supporting Table 3). These Elovl6-related changes occurred in a variety of lipids, including ceramides, cholesterol esters, FFAs, phospholipids (PLs), lysoPLs, sphingomyelins, and TAGs. Conversely, the restoration of hepatic Pnpla3 expression in LKO mice increased the content of six lipid metabolites and reduced the content of 27 metabolites in the liver (Figure 3A and Supporting Table 3). Consistent with a physiologic role of Pnpla3 in determining the TAG and PL composition of hepatic LDs (18-20), Pnpla3 expression altered the

18

distribution of TAG and FFA species, as well as of ceramide and sphingomyelin

species. Among these, the following specific lipids exhibited changes corresponding to

the effects of manipulating Elovl6 and Pnpla3. The concentration of

ceramide(d18:1/18:0) was lower in LKO liver than in Flox liver and was increased by

the restoration of Pnpla3 expression in LKO mice. In contrast, the concentration of

ceramide(d18:2/22:1) was higher in LKO liver than in Flox liver, and was reduced by

the restoration of Pnpla3 expression.

Ceramides have been implicated in the lipid-induced inhibition of insulin sensitivity

(21-23). Moreover, specific ceramide species, which are defined by their fatty

acyl-chain length, can have specific biologic functions (24-26). Therefore, we expanded

our initial lipidomic analysis by analyzing multiple ceramide species to determine

whether their hepatic concentrations are modulated by Elovl6 and Pnpla3. The total

hepatic ceramide content was not significantly affected by genotype, diet, or adenovirus

infection (Supporting Figure 6A), and 19 of the ceramide species evaluated were similar

in abundance between the HSD-fed Flox and LKO mice (Figure 3B). However, Elovl6

deficiency significantly reduced the content of ceramide(d18:1/18:0) and

ceramide(d18:2/18:0) in the liver. In contrast, restoration of Pnpla3 significantly

19

increased the <u>content</u> of ceramide(d18:1/18:0) and ceramide(d18:1/20:0), but

significantly <u>reduced</u> the <u>content</u> of ceramide(d18:2/22:1) in <u>the</u> liver of HSD-fed LKO

mice (Figure 3C). <u>An</u> injection of a small <u>quantity</u> of Pnpla3 adenovirus significantly

increased the <u>content</u> of ceramide(d18:1/16:0) and ceramide(d18:1/18:0), and

significantly <u>reduced</u> the <u>content</u> of ceramide(d18:2/22:1) in the liver of HSD-fed Flox

mice. Elovl6 deficiency significantly reduced the HSD-induced increase in hepatic

ceramide(d18:1/18:0), and this effect was attenuated by <u>the</u> restoration <u>of Pnpla3</u>

<u>expression</u> (Figure 3B, C). Thus, changes in ceramide(d18:1/18:0) concentration <u>are</u>

strongly associated with the insulin sensitivity of LKO mice.

Ceramide(d18:1/18:0) increases PP2A activity and inhibits insulin signaling by

reducing the interaction between PP2A and I2PP2A

<u>Because</u> ceramides are known to regulate insulin sensitivity <u>by activating</u> PP2A and

PKCζ (21-23), we assessed the hepatic activities of PP2A and PKCζ. HSD-feeding

significantly increased PP2A activity in the liver of Flox mice, but not LKO mice

(Figure 3D). <u>The</u> restoration of hepatic Pnpla3 expression in HSD-fed LKO mice

significantly increased PP2A activity to a level comparable to that <u>of</u> HSD-fed Flox

mice (Figure 3D). We also assessed the phosphorylation status of hepatic PKCζ and

20

found that phosphorylation at Thr410, which is required for PKCζ activation (21), was

not altered by Elovl6 deficiency or HSD-feeding (Figure 3E). These results suggest that

the higher hepatic insulin sensitivity in HSD-fed LKO mice may be mediated through

the suppression of C18:0-ceramide production, resulting in a reduction in

ceramide-induced PP2A activity in the liver and lower PP2A-dependent downregulation

of insulin signaling, implying a disinhibition of insulin signaling.

To determine whether ceramide(d18:1/18:0) inhibits insulin signaling, human hepatoma

HepG2 cells were treated with 10 μM ceramide(d18:1/16:0), ceramide(d18:1/18:0), or

ceramide(d18:1/20:0) for 4 h, and with vehicle or insulin for the last 10 min of this

period (Figure 4A). Treatment with ceramide(d18:1/16:0) or ceramide(d18:1/20:0) did

not affect insulin-stimulated phosphorylation of Akt, but ceramide(d18:1/18:0)

treatment significantly suppressed the insulin-stimulated phosphorylation of Akt

compared to vehicle and ceramide(d18:1/16:0) treatment.

Ceramide inhibits insulin signaling by activating PP2A, a serine/threonine phosphatase

that dephosphorylates and thus deactivates Akt (27). Previous studies have

demonstrated that PP2A activity is modulated by phosphorylation at Tyr307 and

21

carboxymethylation at Leu309 of the C subunit (28). Immunoblot analysis revealed that

Elovl6 deficiency and Pnpla3 expression did not affect the levels of phosphorylation or

carboxymethylation of the PP2A C subunit in the liver (Supporting Figure 6B). In

addition, ceramide activates PP2A activity in part via direct binding of Inhibitor 2 of

PP2A (I2PP2A/SET oncogene), which prevents the interaction between PP2A and

I2PP2A (27, 29). Notably, I2PP2A preferentially binds C18-ceramides over C14–C16

ceramides (30, 31). We hypothesized that if the major effect of Elovl6 deficiency on

hepatic insulin signaling is to reduce hepatic ceramide(d18:1/18:0) production, this

effect would be modulated by altering I2PP2A–PP2A binding. To test this hypothesis,

HepG2 cells transfected with HA-tagged PP2A catalytic subunit alpha isoform

(PPP2CA) and FLAG-tagged I2PP2A were treated with ceramide(d18:1/16:0),

ceramide(d18:1/18:0), or ceramide(d18:1/20:0). Ceramide(d18:1/16:0) did not change

the PPP2CA–I2PP2A interaction, but ceramide(d18:1/18:0) and ceramide(d18:1/20:0)

significantly inhibited the PPP2CA–I2PP2A interaction (Figure 4B). This reduction in

the PPP2CA–I2PP2A interaction was much larger in ceramide(d18:1/18:0)-treated cells

than in ceramide(d18:1/20:0)-treated cells.

To confirm the role of I2PP2A in ceramide(d18:1/18:0)-induced insulin resistance,

22

HepG2 cells were infected with lentivirus expressing a short hairpin RNA (shRNA) targeting I2PP2A or a scrambled shRNA (control). Immunoblotting confirmed a significant reduction in the abundance of I2PP2A protein following infection with the specific shRNA (Figure 4C). In HepG2 cells infected with control shRNA, ceramide(d18:1/18:0) reduced the insulin-stimulated phosphorylation of Akt (Figure 4C). Knockdown of I2PP2A reduced the insulin-stimulated phosphorylation of Akt and abrogated the inhibitory effect of ceramide(d18:1/18:0) on the insulin-stimulated phosphorylation of Akt (Figure 4C). Thus, ceramide(d18:1/18:0) inhibits Akt signaling in a I2PP2A-dependent manner to regulate PP2A activity.

To determine the structural basis of the interaction between ceramides and I2PP2A, we performed molecular modeling using the crystal structure of I2PP2A and ceramide(d18:1/16:0), ceramide(d18:1/18:0), or ceramide(d18:1/20:0) as probes, and studied their interactions quantitatively using the first-principles calculations-based fragment molecular orbital method (32). The relative binding scores, the theoretical interaction energies between each ceramide and I2PP2A, from the value of ceramide(d18:1/16:0), are shown in Figure 4D. Consistent with the biologic data, this model suggested that the binding affinity of each species to I2PP2A is in the descending

23

order ceramide(d18:1/18:0), ceramide(d18:1/20:0), and ceramide(d18:1/16:0). Thus, the

potent effect of ceramide(d18:1/18:0) on I2PP2A–PP2A binding shown by *in vivo* and

in vitro assays was also confirmed by a computer simulation.

Ceramide synthase (CerS) associates with Elovl6 and Pnpla3 on the endoplasmic

reticulum (ER) and at the ER-LD interface, respectively

Our findings suggest that both Elovl6 and Pnpla3 are involved in metabolic pathways

that regulating ceramide acyl species. *De novo* ceramide synthesis involves six distinct

CerSs, CerS1 to CerS6, which are specialized for the synthesis of ceramides with

different fatty acyl-chain lengths (26). Therefore, we sought to identify physical

interactions among Elovl6, Pnpla3, and CerS4, a CerS that synthesizes C18–C20

ceramides and is highly expressed in the liver (33).

We first characterized the subcellular distributions of each protein in HEK293 cells

using confocal microscopy. When expressed in HEK293 cells treated with oleate to

increase LD formation, C-terminal FLAG-tagged Elovl6 (Elovl6-FLAG) and V5-tagged

CerS4 (CerS4-V5) displayed a reticular distribution that likely corresponded to the ER

(Supporting Figure 7A). Consistent with previous reports, HA-tagged Pnpla3

24

(Pnpla3-HA) accumulated <u>on</u> membranes and <u>in</u> LDs (Supporting Figure <u>7B</u>). In

co-expression experiments, Elovl6-FLAG appeared to colocalize with CerS4-V5 in the

ER, while Pnpla3-HA and CerS4-V5 appeared to colocalize at the ER-LD interface

upon oleate loading (Figure 5A). When co-expressed with Elovl6-FLAG, Pnpla3-HA

displayed a reticular distribution<u>, likely corresponding to</u> the ER and LDs (Figure 5A).

However, within 24 h <u>of</u> transfection, both Elovl6-FLAG- and Pnpla3-HA-expressing

HEK293 cells were smaller and <u>rounder,</u> with dense cytoplasm and tightly-packed

organelles, <u>suggestive of the induction of</u> apoptosis<u>, which was</u> presumably due to the

greater production of C18:0-ceramide and <u>the higher</u> PP2A activity (27).

We next <u>aimed to identify</u> interactions among Elovl6, Pnpla3, and CerS4 by

immunoprecipitation from co-overexpressing cells. HEK293 cells were transfected with

Elovl6-FLAG and CerS4-V5, Pnpla3-HA and CerS4-V5, or Elovl6-FLAG and

Pnpla3-HA, and then treated with oleate for 24 h. <u>This</u> confirmed the interaction of

Elovl6-FLAG with CerS4-V5 (Figure 5B and Supporting Figure <u>8A), and</u> Pnpla3-HA

was also shown to interact with CerS4-V5 (Figure 5B and Supporting Figure <u>8B</u>).

However, Elovl6-FLAG did not interact with Pnpla3-HA (Figure 5B and Supporting

Figure <u>8C</u>). Taken together, these results suggest that Elovl6 and Pnpla3 may be

25

involved in regulating a pool of C18:0-ceramide by forming Elovl6-CerS4 and

Pnpla3-CerS4 complexes on the ER and at the ER-LD interface, respectively.

Liver-specific deletion of *Elovl6* ameliorates insulin resistance in *ob/ob* mice

To further define the role of hepatic Elovl6 in obesity and insulin resistance, we

assessed the effects of liver-specific *Elovl6* deletion in leptin-deficient *ob/ob* mice, a

widely used animal model of severe obesity, steatohepatitis, and insulin resistance.

Mice with liver-specific disruption of Elovl6 (*ob/ob*-LKO) were severely obese, with

similar body and eWAT weight to those of *ob/ob* mice (Figure 6A). Liver weight was

significantly greater in *ob/ob*-LKO mice than in *ob/ob* mice (Figure 6A), but with

similar degrees of hepatosteatosis (Supporting Figure 9A–C), although there were

prominent differences in FA composition (Supporting Figure 9D). Liver-specific

disruption of *Elovl6* significantly reduced plasma glucose and insulin concentrations

compared to *ob/ob* mice (Figure 6B). OGTTs showed that glucose intolerance was

moderately ameliorated in *ob/ob*-LKO mice *versus* *ob/ob* mice (Figure 6C).

Furthermore, ITTs showed that the insulin resistance was significantly less severe in

ob/ob-LKO mice than in *ob/ob* mice (Figure 6C). The expression of lipogenic genes,

including *Elovl6*, *Srebf1c*, *Fasn*, *Scd1*, and *Pnpla3*, was significantly higher in the livers

26

of *ob/ob* mice than in Flox mice (Figure 6D). However, *ob/ob*-LKO mice showed

significantly lower hepatic expression of these lipogenic genes than *ob/ob* mice. We

also quantified the relative content of representative ceramide species in the livers of

Flox, *ob/ob*, and *ob/ob*-LKO mice and found that the increase in ceramide(d18:1/18:0)

content in *ob/ob* mouse liver was absent in *ob/ob*-LKO mouse liver (Figure 6E).

Moreover, the content of hepatic ceramide(d18:1/20:0), ceramide(d18:1/24:1),

ceramide(d17:1/18:0), ceramide(d17:1/24:1), ceramide(d18:2/18:0), and

ceramide(d18:2/20:0) was significantly lower, and the content of ceramide(d18:1/16:0)

was significantly higher in *ob/ob*-LKO mice than in *ob/ob* mice. The activity of PP2A

in the liver of *ob/ob*-LKO mice was also lower than in *ob/ob* mice (Figure 6F), which

was comparable to the trend identified in Flox mice. Taking these results together, it can

be concluded that hepatic Elovl6-mediated C18:0-ceramide production regulates insulin

sensitivity through the modulation of PP2A activity under lipogenic conditions, and that

liver-specific deletion of Elovl6 can ameliorate insulin resistance in the obese diabetic

state.

DISCUSSION

27

In the present study, we <u>aimed to determine</u> the role of hepatic Elovl6-<u>synthesized</u> long-chain FAs in lipid metabolism and glucose homeostasis by generating liver-specific *Elovl6*-deficient mice. Our results demonstrate that hepatic Elovl6 regulates hepatic insulin sensitivity, in part by affecting the hepatic ceramide FA composition. In turn, ceramide FA composition regulates insulin signaling under lipogenic conditions by modulating <u>the interaction between</u> I2PP2A <u>and</u> PP2A, and PP2A activity. The <u>proposed</u> pathway is presented in Figure 7 and Supporting Figure <u>9E</u>.

<u>There is increasing evidence that diets high in carbohydrate result in greater DNL,</u> <u>obesity, ectopic lipid accumulation, and insulin resistance in animals, as well as in</u> <u>humans (23, 34–36). Hyperglycemia stimulates pancreatic insulin secretion, which,</u> <u>together with dietary carbohydrate, stimulates hepatic DNL by upregulating lipogenic</u> <u>gene transcription. The transcription factors responsible for mediating this include</u> <u>SREBP-1c, which regulates hepatic DNL primarily by regulating the expression of</u> <u>genes involved in DNL, lipid homeostasis, and glucose metabolism (8).</u> *Elovl6* <u>expression is highly responsive to carbohydrates and insulin, and its promoter contains</u>

28

response elements for SREBP-1c (12, 37). *Pnpla3* expression is also strongly induced

by carbohydrate feeding and insulin through the lipogenic transcription factors

SREBP-1c and carbohydrate-response element-binding protein (38, 39). Moreover,

accumulation of long-chain FAs, such as stearate and oleate, the major end-products of

the SREBP-1c pathway, prevents the degradation of the Pnpla3 protein by the

proteasome and stabilize it, thereby increasing its abundance (38). We found that the

expression levels of *Srebf1c* and its target lipogenic genes, including *Acc1*, *Fasn*, *Scd1*,

and *Pnpla3*, were collectively suppressed in the livers of HSD-fed LKO mice. How

does hepatic Elovl6 regulate lipogenic gene expression? On an HSD diet, hepatic Elovl6

deficiency markedly reduced the nuclear levels of SREBP-1, indicating that hepatic

Elovl6 expression and its products are required for the maturation and nuclear

translocation of active SREBP-1 protein. Although the mechanism whereby Elovl6

deficiency reduces the maturation of SREBP-1 protein and *Srebf1c* mRNA expression

remains to be elucidated, a recent study has suggested that the altered acyl-chain

composition of PLs in the ER induced by Elovl6 deficiency may reduce SREBP-1

post-translational processing (40).

Our data demonstrate a novel role for hepatic Elovl6 in the regulation of insulin

signaling. Elovl6 is linked to the generation of ceramide species that activate PP2A by

disrupting interactions with its endogenous inhibitor I2PP2A. Ceramides are bioactive

sphingolipids, mainly composed of a sphingosine backbone and FA chains of variable

length and saturation (26, 41). Several studies have indicated indicate that specific

ceramide species possess distinct physiologic activities (24, 25, 42). In particular,

C16:0-ceramide appears to have a critical role in the pathophysiology of insulin

resistance. For example, mice with global or liver-specific *CerS6* knockout exhibit a

lower C16:0-ceramide concentration and are protected against diet-induced obesity,

insulin resistance, and adipose tissue inflammation (25). A complementary paper found

that heterozygous *CerS2* knockout mice exhibit high C16:0-ceramide concentrations,

hepatosteatosis, glucose intolerance, and insulin resistance (24). The present findings

suggest that hepatic Elovl6 deficiency increases insulin sensitivity by reducing

C18:0-ceramide concentration, which maintains the inhibition of PP2A by I2PP2A,

thereby increasing Akt activity, a key insulin signaling intermediate. Consistent with

this notion, an important role of ceramide(d18:1/18:0) in the development of insulin

resistance has been demonstrated in several studies. In mice, increasing acid ceramidase

expression in the liver reduces the concentrations of C16:0- and C18:0-ceramides and

improves insulin action, implying that these ceramide species may inhibit insulin

30

signaling (42). Luukkonen et al. have recently reported that ceramide(d18:1/18:0) is

among the species that are present in significantly higher concentrations in the livers of

patients with high homeostasis model assessment-insulin resistance, and are most

strongly associated with insulin resistance (43). Moreover, studies in humans have

shown that plasma ceramide(d18:1/18:0) concentration is significantly higher and is

strongly associated with T2D and prediabetes (44, 45). Overall, these results strongly

suggest that C18:0-ceramide suppresses insulin sensitivity. We believe that the present

findings regarding Elovl6 contribute to understanding the molecular mechanisms that

mediate these associations.

Hepatic Pnpla3 is expressed predominantly in hepatocytes, in which it is found on the

ER and LD membrane (38, 46). *In vitro* studies have demonstrated that purified

recombinant human PNPLA3 catalyzes the hydrolysis of the three major glycerolipids,

TAGs, diacylglycerols, and monoacylglycerols, but is most effective with respect to

TAGs (38, 47, 48). A recent *in vitro* study also suggested that Pnpla3 alters the TAG

and PL composition of LDs by catalyzing the transfer of very long-chain PUFAs from

TAGs to PLs (20). The present results suggest that Pnpla3 is involved in the synthesis

of ceramides *in vivo*.

In addition to the ER, our results identify the ER-LD interface as a source of ceramides, and C18:0-ceramide generation is mainly catalyzed by CerS4 in the liver (26, 33). The co-overexpression of Pnpla3 and CerS4 in HEK293 cells suggested that Pnpla3 modifies ceramide FA composition by forming an enzyme complex with CerS4 at the ER-LD interface. Consistent with this result, Senkal *et al*. recently reported that CerSs localize to LDs and form a multi-enzyme complex with acyl-CoA synthetase long-chain family member 5 and diacylglycerol O-acyltransferase 2 at the ER-LD interface, where they generate acylceramides from ceramides and fatty acyl-CoAs (49). Therefore, it is possible that the regulation of ceramide species by Pnpla3 may be facilitated by the release of FAs from hepatic LDs. Pnpla3 is a TAG hydrolase that acts at the surface of LDs, where it releases FAs from TAGs, making them available for incorporation into ceramides. This possibility is supported by a lipidomic study of *ob/ob* mice showing an association between greater deposition of TAG species in the liver and a proportional increase in hepatic ceramide(d18:1/18:0) content (50).

Overall, the results of the present study demonstrate that liver-specific deletion of Elovl6 enhances insulin sensitivity in mice by reducing the generation of ceramides

32

involved in the endogenous activation of PP2A. Although we cannot rule out the possibility that Elovl6 deficiency affects the acyl-chain composition of other lipids that regulate hepatic insulin sensitivity given that our lipidomic platform did not determine the fatty acyl constituents, positional isomers, or double bond positions in the lipid fractions containing PLs, TAGs, and diacylglycerols, the present results strongly suggest that C18:0-ceramide is important in the regulation of insulin sensitivity in lipogenic conditions. Our observations linking Elovl6 and ceramides could thus provide new insight into the pathophysiology of insulin resistance and suggest that inhibition of Elovl6 may represent a therapeutic target for the amelioration of insulin resistance.

enriched (*p* < 0.01) metabolic pathways <u>identified using</u> the KEGG database are shown.

(**C**) mRNA <u>expression</u> of *Elovl6*, *Srebf1c*, and *Pnpla3* in the livers of Flox and LKO

mice fed a chow or HSD for 14 days (n = 15–29 per group). **p < 0.01, ***p < 0.001.

(**D**) Adenovirus-mediated restoration of Pnpla3 expression in the livers of LKO mice.

Immunoblot analysis of Pnpla3 expression in the livers of Flox and LKO mice infected

with adenovirus encoding GFP (Ad-GFP) or Pnpla3 (Ad-Pnpla3). Twelve-week-old

male Flox and LKO mice were fed an HSD for 7 days, <u>then infected</u> with Ad-GFP or

Ad-Pnpla3. After adenovirus infection, <u>the</u> mice were fed an HSD for 7 days. (**E**)

43

Plasma glucose concentrations and AUCs during ITTs in Flox and LKO mice infected

with either Ad-GFP or Ad-Pnpla3 (0.5 U insulin/kg, n = 12–17 per group). *$p < 0.05$,

**$p < 0.01$ for LKO Ad-GFP vs. Flox Ad-GFP mice. #$p < 0.05$, ##$p < 0.01$ for LKO

Ad-Pnpla3 vs. LKO Ad-GFP mice. (**F**) Immunoblot analysis of the insulin signaling

pathway in response to a bolus injection of insulin in the livers of Flox and LKO mice

infected with either Ad-GFP or Ad-Pnpla3. The results were quantified by densitometry

(n = 5 per group). *$p < 0.05$, **$p < 0.01$.

Figure 3. Hepatic insulin sensitivity is associated with changes in the ceramide

profile and PP2A activity

(**A**) Heatmap of the liver lipidomic analysis of HSD-fed Flox and LKO mice infected

with either Ad-GFP or Ad-Pnpla3. The heatmap shows metabolites that were

significantly altered by Elovl6 deficiency or Ad-Pnpla3 infection. The relative content is

indicated by the color. (**B, C**) LC-MS/MS analysis of liver ceramide species from Flox

and LKO mice fed a chow diet or HSD (n = 5 or 6 per group, **B**), or infected with either

Ad-GFP or Ad-Pnpla3 (n = 3–6 per group, **C**). The indicated molecular species were

confirmed by product ion scanning. (**D**) The hepatic PP2A activity of Flox and LKO

mice fed a normal chow or HSD (n = 6–9 per group) or infected with either Ad-GFP

44

(GFP) or Ad-Pnpla3 (P3, n = 5–7 per group). The phosphatase activity of the

immunoprecipitated PP2A was quantified using a phosphatase activity assay. (**E**)

Immunoblot analysis of phosphorylated PKCζ and total PKCζ in the livers of Flox and

LKO mice fed a normal chow or HSD. The ratio of phosphorylated to total PKCζ was

determined by densitometry (n = 4 per group). *$p < 0.05$, **$p < 0.01$, ***$p < 0.001$.

Figure 4. Ceramide(d18:1/18:0) inhibits the I2PP2A–PP2A interaction and insulin-induced phosphorylation of Akt in HepG2 cells

(**A**) Immunoblot analysis of Akt phosphorylation in response to insulin treatment of

HepG2 cells pretreated with ceramide(d18:1/16:0), ceramide(d18:1/18:0),

ceramide(d18:1/20:0), or vehicle. Cells were pretreated with media containing vehicle

or 10 μM ceramide for 4 h before insulin stimulation. The ratio of phosphorylated to

total Akt was determined using densitometry (n = 6 per group). (**B**) Effect of ceramide

species on the interaction between PP2A and I2PP2A. HepG2 cells were incubated with

the indicated ceramide for 4 h. The PP2A–I2PP2A interaction was determined by

immunoprecipitation using an anti-FLAG antibody, followed by immunoblotting using

anti-HA and anti-FLAG antibodies. The PP2A–I2PP2A interaction was quantified using

densitometry (n = 6 per group). (**C**) Effect of I2PP2A knockdown on insulin-induced

45

Akt phosphorylation in HepG2 cells treated with 10 mM ceramide for 4 h. The ratio of

phosphorylated to total Akt was determined using densitometry (n = 5 per group). (**D**)

Molecular docking simulations of ceramide(d18:1/16:0), ceramide(d18:1/18:0), and

ceramide(d18:1/20:0) with I2PP2A, and van der Waals interaction energy between the

ceramides and amino acid residues of I2PP2A. Hydrophobic and hydrophilic residues

are shown in red and blue, respectively. *$p < 0.05$, **$p < 0.01$, ***$p < 0.001$.

Figure 5. CerS4 interacts with Elovl6 and Pnpla3

HEK293 cells were transfected with FLAG-tagged Elovl6, HA-tagged Pnpla3, and (or)

V5-tagged CerS4. (**A**) Co-localizations of Elovl6-FLAG with CerS4-V5, Pnpla3-HA

with CerS4-V5, and Elovl6-FLAG with Pnpla3-HA were identified using confocal

microscopy. Scale bar = 10 μm. (**B**) Interactions among Elovl6, Pnpla3, and CerS4

determined by immunoblotting after immunoprecipitation using the indicated

antibodies.

Figure 6. Hepatic deletion of Elovl6 ameliorates insulin resistance in *ob/ob* mice

(**A**) Body, liver, and eWAT weights of 12-week-old Flox, *ob/ob*, and *ob/ob*-LKO mice

(n = 17−25 per group). (**B**) Plasma glucose and insulin concentrations of 12-week-old

46

Flox, *ob/ob*, and *ob/ob*-LKO (n = 17–25 per group). (**C**) Plasma glucose concentration

during OGTTs (n = 14–22 per group) and ITTs (2.0 U insulin/kg, n = 10 or 11 per

group), and AUCs during the ITT (n = 10 or 11 per group) in 12-week-old Flox, *ob/ob*,

and *ob/ob*-LKO mice. (**D**) qPCR analysis of genes involved in DNL in livers of Flox,

ob/ob, and *ob/ob*-LKO mice (n = 16–21 per group). (**E**) LC-MS/MS analysis of liver

ceramide species from Flox, *ob/ob*, and *ob/ob*-LKO mice. The indicated molecular

species were confirmed by product ion scanning (n = 3 or 4 per group). (**F**) Liver PP2A

activity of Flox, ob/ob, and ob/ob-LKO mice (n = 5 or 6 per group). *$p < 0.05$, **$p <$

0.01, ***$p < 0.001$.

Figure 7. Schematic description of the Elovl6/Pnpla3/CerS pathway regulating

hepatic insulin signaling

Excess consumption of carbohydrate and hyperinsulinemia activate *de novo* lipogenesis

and upregulate the expression of Elovl6 and Pnpla3 in the liver. Activation of Elovl6

increases the amount of C18:0, enhancing C18:0-ceramide production through

formation of an enzyme complex with CerS4 on the ER. Pnpla3 acts on the surface of

LDs, releases FAs from TAGs, and modifies ceramide FA composition by forming an

enzyme complex with CerS4 at the ER-LD interface. Both Elovl6 and Pnpla3 are linked

47

to the generation of C18:0-ceramide, which activates PP2A by disrupting the interactions with its endogenous inhibitor I2PP2A. As a consequence, PP2A inhibits insulin signaling by impairing Akt activation.

Figure 7. Schematic description of the Elovl6/Pnpla3/CerS pathway regulating hepatic insulin signaling

SUPPORTING INFORMATION

Hepatocyte Elovl6 determines ceramide acyl-chain length and hepatic insulin sensitivity in mice

Takashi Matsuzaka, Motoko Kuba, Saori Koyasu, Yuta Yamamoto, Kaori Motomura, Sundaram Arulmozhiraja, Hiroshi Ohno, Rahul Sharma, Takuya Shimura, Yuka Okajima, Song-iee Han, Yuichi Aita, Yuhei Mizunoe, Yoshinori Osaki, Hitoshi Iwasaki, Shigeru Yatoh, Hiroaki Suzuki, Hirohito Sone, Yoshinori Takeuchi, Naoya Yahagi, Takafumi Miyamoto, Motohiro Sekiya, Yoshimi Nakagawa, Masatsugu Ema, Satoru Takahashi, Hiroaki Tokiwa, and Hitoshi Shimano

SUPPORTING MATERIALS AND METHODS

Materials.

Human insulin was obtained from Novo Nordisk. HepG2 and HEK293 cells were

purchased from American Type Culture Collection (ATCC). Ceramide(d18:1/16:0),

ceramide(d18:1/18:0), and ceramide(d18:1/20:0) were purchased from Avanti Polar

Lipids. Antibodies against phospho-insulin receptor (Tyr972) (Cat# 07-838; RRID:

AB_568829), insulin receptor beta subunit (Cat# 07-724; RRID: AB_11213944), IRS-1

(Cat# 05-1085; RRID: AB_1977296), and IRS-2 (Cat# 06-506; RRID: AB_10615782)

were obtained from Millipore. Antibodies against phospho-Akt (Ser473) (Cat# 4060;

RRID: AB_2315049), phospho-Akt (Thr308) (Cat# 13038; RRID: AB_2629447), Akt

(pan) (Cat# 4691; RRID: AB_915783), phospho-Tyrosine (Cat# 3089; RRID:

AB_331228), lamin A/C (Cat# sc-8984; RRID: AB_2136278), phospho-PKC zeta

(Thr410) (Cat# 2060; RRID: AB_561487), PKC zeta (Cat# 9368; RRID:

AB_10693777), DYKDDDDK-Tag (Cat# 14793; RRID: AB_2572291), V5-Tag (Cat#

13202; RRID: AB_2687461), and glyceraldehyde-3-phosphate dehydrogenase

(GAPDH) (Cat# 5174; RRID: AB_10622025) were obtained from Cell Signaling

Technology. Antibodies against PNPLA3 (Cat# ab81874; RRID: AB_10712485), SET

(Cat# ab181990; RRID: AB_2737445), and Calreticulin (Cat# ab92516; RRID: AB_10562796) were obtained from Abcam. Antibodies against PKC epsilon (Cat# sc-214; RRID: AB_2237729) and SREBP-1 (Cat# 9411; RRID: AB_2194223) were obtained from Santa Cruz Biotechnology. Antibodies against DDDDK-Tag (Cat# PM020; RRID: AB_591224) and HA-tag (Cat# M180-3; RRID: AB_10951811) were obtained from MBL International. Antibody against V5-Tag (Cat# R960-25; RRID: AB_255656) was obtained from Thermo Fisher Scientific. Anti-DDDDK-tag mAb-Magnetic Agarose (Cat# M185-10), anti-HA-tag mAb-Magnetic Agarose (Cat# M180-10), and Anti-V5-tag mAb-Magnetic Agarose (Cat# M167-10) were purchased from MBL International. Tristearin and triolein were purchased from Tokyo Chemical Industry and FUJIFILM Wako Chemicals, respectively.

Generation of liver-specific *Elovl6* knockout mice.

The targeting vector for *Elovl6* gene disruption was constructed by ligation of three polymerase chain reaction (PCR) fragments into a conditional targeting vector cassette (51). The targeting vector was linearized and transfected into C57BL/6J mouse embryonic stem (ES) cells (52). ES cells that integrated the targeting vector either by homologous or random integration were selected by growth on G418. The anticipated

homologous recombination was subsequently confirmed by PCR and Southern hybridization. ES cells harboring the homologous integration were injected into ICR mouse blastocysts to generate chimeric mice. Male mice chimeric for the targeted allele were mated with female Flpe-transgenic mice to remove the Neo cassette and generate a floxed *Elovl6* allele (*Elovl6*$^{lox/+}$). Offspring *Elovl6*$^{lox/+}$ mice were intercrossed with C57BL/6J Albumin-Cre mice (stock No: 003574, Jackson Laboratory) to generate compound heterozygous (*Elovl6*$^{lox/+;Cre/+}$) mice. Compound heterozygous mice were crossed with *Elovl6*$^{lox/lox}$ mice to obtain *Elovl6*$^{lox/lox;Cre/+}$ (liver-specific Elovl6 knockout: LKO) mice. Genotyping was performed by PCR using genomic DNA isolated from the tail tip as previously described (3). The primer sequences for the Cre transgenes are available from the Jackson Laboratory (https://www2.jax.org/protocolsdb/f?p=116:5:0::NO:5:P5_MASTER_PROTOCOL_ID, P5_JRS_CODE:20627,003574). For Elovl6 lox genotyping, we used primers 5'-GCTCAGCAGCCTTCCTGTGAG-3' (P1) and 5'-TCCACTGGACAGAGTGGCTTC-3' (P2). Age-matched male littermates were used in all experiments. We sacrificed mice during the early light phase, after a 4-h fast.

Elovl6 enzyme activity assay.

Elovl6 enzyme activity was determined in liver microsomes by measuring [2-^{14}C]malonyl-CoA incorporation into exogenous palmitoyl-CoA as described previously (12, 13).

Fatty acid composition of liver.

Total lipids in liver were extracted using Bligh–Dyer's procedure, and the relative abundances of each FA were measured quantitatively by LC-MS/MS as described previously (53).

Metabolic measurements.

Glucose, insulin, triglyceride (TAG), total cholesterol (T-Cho), free fatty acid (FFA), alanine aminotransferase (ALT), and aspartate aminotransferase (AST) levels in plasma and TAG and T-Cho levels in liver were determined as described previously (13, 54). For the oral glucose tolerance test (OGTT), mice were orally administrated D-glucose (1 g/kg body weight) after an overnight fast (16 h). For the insulin tolerance test (ITT), mice were injected intraperitoneally with regular human insulin (Eli Lilly Japan) after a 4-h fast. Blood samples were collected before injection and at specific times after injection (indicated in figures) to determine glucose and insulin levels. Hepatic TAG

and T-Cho levels were measured as described previously (13).

In vivo **insulin stimulation assay.**

Mice were fasted for 4 h and anesthetized by injection of 30 mg/kg pentobarbitone (Kyoritsu Seiyaku, Tokyo, Japan). We then opened the peritoneal cavity and injected either saline control or insulin (0.5 units/kg) into the inferior vena cava. After 1.5 min, the livers were rapidly excised and immediately frozen in liquid nitrogen. We performed immunoprecipitation and immunoblot analysis of insulin signaling molecules using tissue homogenates.

Dietary fat supplementation.

Twelve-week-old male Flox and LKO mice were fed with HSD or HSD supplemented with 20% (w/w) tristearin (C18:0) plus 20% triolein (C18:1n-9) for 14 days.

Preparation of recombinant adenovirus and animal transduction.

Adenoviruses expressing full-length mouse Pnpla3 (Ad-Pnpla3) or GFP (Ad-GFP) control were prepared as described (13). Adenoviruses were injected into the mice via the tail vein at 1×10^9 plaque-forming units. Mice were sacrificed for analysis on day 7

after viral injection.

Microarray analysis.

Total RNA was extracted using the NucleoSpin RNA Kit (TaKaRa Bio, Shiga, Japan) according to the manufacturer's instructions. To determine the quality of RNA, the RNA Integrity Number (RIN) was measured using the Agilent 2100 Bioanalyzer. Microarray analysis was performed with the SurePrint G3 Mouse Gene Expression 8X60K Microarray Kit (#G4852A, Agilent Technologies). Data were analyzed by Expressionist Analyst software version 8.2.7b (Genedata AG, Basel, Switzerland). Heatmaps were generated using Multi Experiment Viewer (MeV) software (http://www.tm4.org/mev.html). Pathway analysis was performed using GO and KEGG analysis systems provided by DAVID v6.8 (https://david.ncifcrf.gov/). The raw data are available in the Gene Expression Omnibus (GEO) database (GSE123494).

RNA extraction and quantitative real-time PCR analysis.

Total RNA extraction from liver, cDNA synthesis, and quantitative real-time PCR (qPCR) were performed as previously described (13, 54, 55). For the qPCR of *Pnpla3*, we used primers 5'-TCACCTTCGTGTGCAGTCTC-3' (forward) and

5'-CCTGGAGCCCGTCTCTGAT-3' (reverse). For the qPCR of *Pnpla5*, we used

primers   5'-ACACTGCCCTTCGAGTATGC-3'   (forward)   and

5'-CAGGATGCTCCTCATCCAAT -3' (reverse).   mRNA expression levels were

normalized to that of cyclophilin mRNA and expressed relative to the appropriate

experimental control using the ∆∆CT method.

Immunoblotting.

Immunoblotting was performed as described previously (3). Aliquots of whole cell

lysate (50 μg), membrane fraction (25 μg), and nuclear extract (25 μg) proteins from

liver, WAT, or skeletal muscle were loaded onto SDS-PAGE gels, separated, and

transferred to PDVF membranes. The membranes were probed with primary antibodies

overnight at 4 °C, followed by labeling with horseradish peroxidase (HRP)-conjugated

secondary antibody against mouse or rabbit IgG (Cell Signaling Technology Japan,

Tokyo, Japan). Immune complexes were visualized using enhanced chemiluminescence

(Bio-Rad Laboratories, Hercules, CA, USA). The intensity of the bands was quantified

using ImageJ software (National Institutes of Health) and normalized to β-actin or

GAPDH.

Metabolite profiling analysis in the MxP Lipids platform.

The MxP® Lipids platform (Metanomics Health GmbH, Berlin, Germany) was used for the entire lipid analysis workflow. The total lipid content of freeze-dried, homogenized liver tissue was extracted using chloroform/methanol. The lipid extracts were subsequently fractionated using normal phase liquid chromatography into 11 different lipid groups. The lipid fractions containing cholesterol esters (CEs), sphingomyelins (SMs), and ceramides were analyzed by liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS) using electrospray ionization and atmospheric pressure chemical ionization with detection of specific multiple reaction monitoring transitions. The lipid fractions containing monoacylglycerols, diacylglycerols, triacylglycerols (TAG), phosphatidylcholines, phosphatidylserines, phosphatidylinositols, lysophosphatidylcholines and FFAs were analyzed by gas chromatography-flame ionization detection after derivatization with trimethyl sulfonium hydroxide to yield FA methyl esters corresponding to the acyl moieties of the class-separated lipids. The concentrations of FA methyl esters in the C14–C24 range were determined in each fraction.

Metabolite profiling based on a semi-quantitative analytical platform yields relative metabolite levels ("ratios") to a defined reference. To support this concept and

allow alignment of different analytical batches, two different reference sample types were run in parallel throughout the whole process. First, a project pool was generated from aliquots of all samples and measured with four replicates within each analytical sequence of 24 samples. For all semi-quantitatively analyzed metabolites, the data were normalized against the median of the pooled reference sample within each analytical sequence to provide pool-normalized ratios (performed for each sample per metabolite). This processing step compensated for inter- and intra-instrumental variation, i.e., normalized the variability that occurs when different analytical sequences are analyzed by different devices. The limit of detection and the dynamic range of the semi-quantitative measurements were determined by dilution and spiking experiments during method development. The term "additional" (add.) was applied to metabolite names when the quantification was disturbed by metabolites exhibiting identical analytical characteristics with respect to the quantitation method.

Prior to statistical analysis, log10 transformation of ratios was conducted so that the data distribution was approximately normal. SIMCA-P version 13.0 (Umetrics AB, Umea, Sweden), TIBCO Spotfire 3.3.1, and R 2.8.1 were used for data analyses and visualization. Initially, an exploratory multivariate analysis [Principal Component Analysis (PCA)] was applied to log10-transformed ratios scaled to unit variance. A

mixed linear model (ANOVA, R package nlme) with "genotype," "adenovirus," and "adenovirus:genotype," as fixed effects was fitted to the data. Significance level was set to 5%. The multiple test problem was addressed by calculating the false discovery rate (FDR) using the Benjamini & Hochberg method (56).

Targeted ceramide profiling analysis.

Total lipids were extracted from freeze-dried, homogenized liver tissue using chloroform/methanol containing 1% acetic acid and the internal standards. The lipid extracts were subjected to ceramide profiling by liquid chromatography tandem mass spectrometry (LC-MS/MS) using a UltiMate3000 BioRS system (Thermo Fisher Scientific) coupled to a 3200QTRAP triple quadrupole mass spectrometer (SCIEX) equipped with an ESI source. LC separation was achieved using a reverse-phase *L-column2 C8* metal-free column (3 μm particle size, 2.1 mm i.d. × 100 mm; Chemicals Evaluation and Research Institute, Tokyo, Japan) at 40 °C. Sample injection volume was 3 μL, flow rate was 0.3 mL/min, and sampler temperature was 4°C. Mobile phase A consisted of ultra-pure water/acetonitrile (1:1) with 1 mM ammonium formate and mobile phase B of acetonitrile/2-propanol (1:9). The targeted analyses were performed in positive multiple reaction monitoring mode. We used ceramide(d18:1/17:0) as an

internal standard and ceramide(d18:1/18:0) for the preparation of standard solution.

Samples were measured in triplicate. MS data were acquired and processed using the

Xcalibur 3.0 software package. Lipid Search (Mitsui Knowledge Industry, Tokyo,

Japan) was used for lipid molecular species identification and quantification.

Protein phosphatase 2A (PP2A) activity assay.

The PP2A activity in liver lysates were measured using a PP2A Immunoprecipitation

Phosphatase Assay kit (Merck Millipore, Darmstadt, Germany), according to the

manufacturer's protocol.

Lentivirus production and transduction.

Lentivirus production and transduction were performed as described previously (57).

MISSION TRC shRNA target sets for human I2PP2A (TRCN0000063716 and

TRCN0000063717) and negative control (nontarget; SHC002) were purchased from

Sigma-Aldrich (St. Louis, MO, USA). Generation and infection of lentivirus were

performed according to the manufacturer's instructions.

Molecular modeling of I2PP2A with ceramides.

The complex structures of I2PP2A during interactions with ceramide(d18:1/16:0), ceramide(d18:1/18:0), and ceramide(d18:1/20:0) were constructed using the Molecular Operating Environment (MOE) program (Chemical Computing Group, https://www.chemcomp.com/MOE-Molecular_Operating_Environment.htm) by combining I2PP2A X-ray structures (PDB ID: 2E50). The preliminary structure optimization was performed by molecular mechanics calculations utilizing the Amber10EHT force field with solvation energy accounted via the Born model. The constructed structure was subjected to molecular dynamics (MD) simulations up to 500 ps to analyze the stability of modelled structures. The initial setups for the MD simulations were made by using the AMBER14 program (http://ambermd.org/) utilizing ff14SB force field. The MD simulations were performed with explicit solvent water molecules. AMBER topology files created using AMBER were converted to GROMACS format using acpype.py script (58). All the MD simulations were performed using the GROMACS package (http://www.gromacs.org/). Calculations were run at 300 K and a pressure of 1 bar, with the NPT ensemble. FMO calculations were carried out using the PAICS program (59). The correlated Resolution-of-Identity second-order Moller Plesset (RI-MP2) level of theory with correlation-consistent double ζ basis set cc-pVDZ was used for the FMO calculations.

Culture of HepG2 cells, ceramide treatment, and insulin stimulation.

Human hepatocellular carcinoma HepG2 cells were cultured in Dulbecco's Modified

Eagle's Medium (DMEM) supplemented with 10% fetal bovine serum and 1%

penicillin/streptomycin. For ceramide treatment, HepG2 cells were seeded into collagen

I-coated 60-mm dishes and cultured in serum-free DMEM supplemented with 0.5%

FA-free bovine serum albumin. Then, the cells were permeabilized with 20 μg/mL

digitonin for 5 min and incubated for 4 h with C16–C20 ceramide solubilized in 2%

dodecane/98% ethanol solution. In addition, some cells were treated with insulin (100

nM) for 10 min.

Culture of HEK293 cells, plasmid construction, transfection, and immunoprecipitation.

Human Embryonic Kidney 293 (HEK293) cells were cultured in DMEM supplemented

with 10% FBS and 1% penicillin/streptomycin. cDNAs encoding C-terminal

FLAG-tagged Elovl6, C-terminal HA-tagged Pnpla3, and C-terminal V5-tagged CerS4

were cloned separately into the pcDNA3.1 plasmid. Cells were transiently transfected

with the indicated plasmid combinations using Lipofectamine 3000 (Life Technologies

Corporation, NY, USA) according to the manufacturer's protocol. Anti-FLAG,

anti-HA, and anti-V5 immunoprecipitations were performed by incubating cell lysates

with anti-FLAG, anti-HA, and anti-V5 magnetic agarose antibodies (MBL, Nagaya,

Japan), respectively, overnight on an end-to-end rotator at 4 °C. The

immunoprecipitated complexes were washed with excess volumes of lysis buffer before

SDS-PAGE separation and immunoblotting.

Immunofluorescence and confocal microscopy analysis.

HEK293 cells were plated on 35-mm dishes with poly-lysine-coated glass bottoms

(Matsunami Glass, Osaka, Japan), and were transiently transfected with the indicated

plasmid using Lipofectamine 3000 (Life Technologies Corporation, NY, USA)

according to the manufacturer's protocol. Cells were then washed with 1× phosphate

buffered saline (PBS), fixed with 4% (w/v) paraformaldehyde in 1× PBS for 15 min,

washed and permeabilized with 0.1% Triton X-100 in PBS for 5 min, washed three

times with 1× PBS, and blocked in 1% (w/v) FA-free BSA containing 1× PBS for 1 h.

After incubation with primary antibodies at 1:500 dilution in 1% BSA solution, cells

were washed in PBS and incubated with secondary antibodies conjugated to Alexa

Fluor dyes (Life Technologies Corporation, NY, USA) for 1 h. For the detection of

LDs, cells were incubated with 10 μM BODIPY 493/503 (Thermo Fisher Scientific,

MA, USA) for 1 h. Dishes were mounted with VECTEASHIELD Mounting Medium

and DAPI (Vector Laboratories, CA, USA). Immunofluorescence was performed using

a TCS SP5 confocal microscope (Leica, Wetzlar, Germany), and images and overlays

were analyzed using LAS AF software (Leica, Wetzlar, Germany).

SUPPORTING DISCUSSION

We have previously shown that global Elovl6 deficiency prevents diet-induced insulin resistance by modifying hepatic FA composition (13). However, unexpectedly, we found that LKO mice were not protected from HFHS diet-induced insulin resistance. We interpret this result as indicating that the deletion of *Elovl6* in hepatic non-parenchymal cells, such as Kupffer cells and stellate cells, or in extrahepatic tissues, such as adipose tissue, skeletal muscle, and intestine, may be necessary to generate a protective effect of Elovl6 inhibition on mice fed an HFHS diet.

Our results also show a positive correlation between ceramide(d18:2/22:1) and insulin sensitivity. However, we could not determine the direct effect of ceramide(d18:2/22:1) on insulin sensitivity because there is no commercially available standard or this ceramide and it is difficult to chemically synthesize it. Moreover, to our knowledge, there have been no reports regarding the role of ceramide(d18:2/22:1) in cell physiology and disease. Future studies should aim to determine the physiologic and clinical relevance of this ceramide for insulin resistance and disease in humans.

Although PP2A and PKCζ are downstream targets of ceramide modulation, their roles

in DNL-dependent insulin sensitivity have not been evaluated. Here we show that a

reduction in PP2A activity, but not in PKCζ activity, was associated with higher insulin

sensitivity in HSD-fed LKO mice, suggesting that the activation of hepatic PP2A

depends on the production of ceramides by Elovl6. Because Elovl6 and Pnpla3 are

nutritionally regulated, as SREBP-1 targets, and are crucial for ceramide formation, the

acyl-CoAs used for ceramide synthesis are likely derived from DNL and TAGs in LDs.

Another possible impact of Elovl6 deficiency on ceramide metabolism is activation of

the *de novo* synthesis of ceramide. It is likely that greater palmitoyl-CoA accumulation

in LKO hepatocytes activates *de novo* ceramide synthesis because palmitoyl-CoA and

L-serine are precursors for the sphingolipid biosynthesis (22). Thus, suppression of

C18:0-ceramide in the liver of LKO mice may result from a combination of the

activation of *de novo* ceramide synthesis and a reduction in C18:0 synthesis.

SUPPORTING FIGURE LEGENDS

Supporting Figure 1. Generation of liver-specific Elovl6 knockout mice

(**A**) Schematic representation of the mouse *Elovl6* gene. Each box represents one exon.

The black boxes represent the *Elovl6* coding exons (numbered) and open boxes indicate

non-coding regions. (**B**) Targeting strategy for conditional deletion of the *Elovl6* gene.

The targeting construct contains the fifth exon (the conserved HXXHH motif and the 3'

untranslated region-containing exon) of *Elovl6* flanked by three loxP sites and the

PGK-neo cassette (Neo) flanked by FRT sites. Neo was removed by crossing with mice

expressing FLPe under control of the human β-actin promoter. *Elovl6* exon 5 was

deleted by mating *Elovl6* Flox+/− mice with Albumin-Cre mice. Arrows to P1 and P2

indicate the positions of primers for genotyping. We confirmed homologous

recombination between the targeting vector and Elovl6 locus in C57BL6/J mouse

embryonic stem (ES) cells by polymerase chain reaction (PCR) and Southern

hybridization (data not shown). Chimeric mice were obtained by microinjecting Elovl6

flp/+ ES cells into mouse blastocysts, and the resulting animals were crossed with

C57BL/6J mice to achieve germ line transmission of the floxed allele. Next, Elovl6

lox/+ mice were mated with the general deleter mouse ACTB-FLPe to remove the

phosphoglycerokinase (PGK) neomycin resistance (neo) cassette, which might produce

unwanted side effects, by excisional recombination of the Flp/FRT system. Elovl6

lox/lox mice were successfully generated by mating male and female Elovl6 lox/+ mice.

Elovl6 lox/lox (Flox) mice were phenotypically indistinguishable from wild-type mice

and showed normal Elovl6 mRNA expression and Elovl6 enzyme activity (data not

shown), indicating the loxP sites did not interfere with Elovl6 expression. To generate

liver-specific Elovl6 deficient mice, we crossed Elovl6 lox/lox mice to albumin

promoter-Cre transgenic mice expressing Cre exclusively in postpartum hepatocytes to

obtain Elovl6 lox/+;Cre+ mice. Subsequently, we crossed these mice to Flox mice to

yield Elovl6 lox/lox;Cre+ (LKO) mice. LKO mice were born at a Mendelian ratio and

newborns were physically indistinguishable from their control littermates, nursed

successfully, weaned normally, and were active and fertile. (**C**) The genotype of mice

harboring the null allele was confirmed by PCR using tail genomic DNA and primers

P1 and P2 indicated in B to amplify a 304-bp product from the wild-type (WT) allele

and a 376-bp product from the Elovl6 floxed allele (upper panel). Another PCR yielded

a 100-bp band for the Cre transgene (lower panel). (**D**) qPCR analysis of *Elovl6* mRNA

expression levels in various tissues. This analysis confirmed that the *Elovl6* gene

deletion in LKO mice was restricted to the liver. Results are expressed as mean ± SEM

of n = 12 mice per group. ***$p < 0.001$ for LKO vs. Flox mice. (**E**) Hepatic Elovl6 activity was measured in the presence of 50 μg microsomal protein, NADH, and ^{14}C-palmitoyl-CoA. This assay further confirmed effective loss of activity in the liver of LKO mice. Results are expressed as mean ± SEM of n = 6 mice per group. ***$p < 0.001$ for LKO vs. Flox mice. (**F**) Fatty acid composition of LKO and Flox mouse liver. Mice were fed a high-carbohydrate, fat-free diet for 3 days. Consistent with lack of hepatic Elovl6 activity, LKO mice had lower levels of Elovl6 products in liver, including stearate (C18:0) and oleate (C18:1n-9), and higher levels of palmitate (C16:0), palmitoleate (C16:1n-7), and vaccinate (C18:1n-7). These results demonstrate successful disruption of *Elovl6* in liver. Results are expressed as mean ± SEM of n = 3 mice per group. *$p < 0.05$, **$p < 0.01$, ***$p < 0.001$.

Supporting Figure 2. LKO mice are not protected from high-fat and high-sucrose (HFHS) diet-induced obesity and insulin resistance

(**A**) Body weight changes of 8-week-old male Flox and LKO mice fed a chow or HFHS diet for 12 weeks (n = 12–22 per group). (**B**) Weights of liver and eWAT from Flox and LKO mice fed a chow or a HFHS diet for 12 weeks (n = 15–20 per group). (**C**) Hepatic TAG and T-Cho levels of Flox and LKO mice fed a chow or HFHS diet for 12 weeks (n

= 12–16 per group). (**D**) Plasma concentrations of glucose and insulin of Flox and LKO

mice fed a chow or HFHS diet for 12 weeks (n = 14 or 15 per group). (**E**) Plasma

glucose and insulin concentrations during oral glucose tolerance tests (OGTTs) for Flox

and LKO mice fed a chow or HFHS diet for 12 weeks (n = 10–14 per group). (**F**)

Insulin tolerance tests (ITTs) for Flox and LKO mice fed a chow (0.5 U insulin per kg

of body weight) or HFHS diet (1.0 U insulin per kg of body weight) (n = 12–25 per

group). Results are expressed as mean ± SEM. *$p < 0.05$, **$p < 0.01$, ***$p < 0.001$.

Supporting Figure 3. Body and tissue weights, plasma concentrations of metabolic

parameters, liver histology, and hepatic protein levels of Flox and LKO mice fed

either a chow or HSD

(**A**) Body, liver, and eWAT weight in 12-weeks-old male Flox and LKO mice fed either

a chow or HSD for 14 days (n = 16–23 mice per group). (**B**) Plasma triacylglycerol

(TAG), total cholesterol (T-Cho), free fatty acid (FFA), and alanine aminotransferase

(ALT) levels in Flox and LKO mice fed either a chow or HSD for 14 days (n = 15–24

mice per group). (**C**) Hematoxylin and eosin (H&E) staining of liver sections from

representative mice from each group. Scale bar = 50 μm. (**D**) Phosphorylation of IRS-1

and IRS-2 induced by a bolus injection of insulin in livers of Flox and LKO mice on an

HSD. Blots are representative of three independent experiments. IP, immunoprecipitated; IB, immunoblotted; pY, phosphorylated tyrosine. (**E**) Immunoblot analysis of membrane and cytosolic PKCε contents in the livers of Flox and LKO mice fed an HSD for 14 days. Blots are representative of three independent experiments. Results are expressed as mean ± SEM of n = 6 mice per group. (**F**) Immunoblot analysis of Akt phosphorylation in response to bolus injection of insulin into eWAT and skeletal muscle of Flox and LKO mice fed an HSD for 14 days. Blots are representative of three independent experiments. *$p < 0.05$, **$p < 0.01$.

Supporting Figure 4. Effects of stearate and oleate supplementation and HSD feeding in LKO mice

(**A**) ITTs (0.5 U insulin per kg of body weight) for 12-weeks-old male Flox and LKO mice fed either an HSD or HSD supplemented with stearate (C18:0) and oleate (C18:1n-9) for 14 days (n = 9–15 per group). (**B**) Immunoblot analysis of SREBP-1 in the membrane fraction and nuclear extract, and lamin A/C protein in the nuclear extract from livers of Flox and LKO mice fed a regular chow diet or HSD. (**C**) qPCR analysis of lipogenic genes in the livers of Flox and LKO mice fed a chow or HSD (n = 15–29 per group). (**D**) The volcano plot of microarray analysis for differentially expressed

transcripts in the livers of HSD-fed Flox and LKO mice. Significantly up- and down-regulated genes are represented in green and orange respectively. (**E**) *Pnpla5* expression in the livers of Flox and LKO mice fed either a chow or HSD (n = 8–13 per group). (**F**) Immunoblot analysis of Pnpla3 expression in the livers of Flox and LKO mice fed a chow or HSD. *p < 0.05, **p < 0.01, ***p < 0.001.

Supporting Figure 5. Effects of adenovirus-mediated Pnpla3 restoration in LKO mice

(**A**) Body and liver weight in 12-weeks-old male Flox and LKO mice infected with either Ad-GFP or Ad-Pnpla3 (n = 9–16 per group). (**B**) Hepatic TAG and T-Cho levels in Flox and LKO mice infected with either Ad-GFP or Ad-Pnpla3 (n = 7–10 per group). (**C**) H&E staining of liver sections from representative mice from each group. Scale bar = 100 μm. (D) Plasma ALT and aspartate aminotransferase (AST) levels in Flox and LKO mice infected with either Ad-GFP or Ad-Pnpla3 (n = 17–20 per group). **p < 0.01, ***p < 0.001.

Supporting Figure 6. Effects of HSD feeding and adenovirus-mediated Pnpla3 restoration on ceramide contents and post-translational modification of PP2A in

the livers of Flox and LKO mice

(**A**) Relative levels of ceramide in the livers of 12-weeks-old male Flox and LKO mice fed either a chow or HSD for 14 days (n = 3–6 per group) or infected with either Ad-GFP or Ad-Pnpla3 for 7 days (n = 5–6 per group). (**B**) Immunoblot analysis of PP2A phosphorylation (Thr307) and methylation (Leu309) in the livers of Flox and LKO mice fed either a chow or HSD or infected with either Ad-GFP or Ad-Pnpla3. Blots are representative of three independent experiments.

Supporting Figure 7. Subcellular co-localization of FLAG-tagged Elovl6, HA-tagged Pnpla3, and V5-tagged CerS4 with ER and LD markers

(**A**) HEK293 cells were transfected with FLAG-tagged Elovl6, HA-tagged Pnpla3, and V5-tagged CerS4. Co-localization of Elovl6-FLAG, Pnpla3-HA, and CerS4-V5 with the ER marker calreticulin as imaged by confocal microscopy in the presence of 200 μM oleate. Scale bar = 10 μm. (**B**) Co-localization of Elovl6-FLAG, Pnpla3-HA, and CerS4-V5 with LDs detected by BODIPY as imaged by confocal microscopy in the presence of 200 μM oleate. Scale bar = 10 μm.

Supporting Figure 8. CerS4 associates with Elovl6 and Pnpla3

(**A-C**) HEK293 cells were transfected with FLAG-tagged Elovl6, HA-tagged Pnpla3, and (or) V5-tagged CerS4. Interactions of Elovl6 with CerS4 (**A**), Pnpla3 with CerS4 (**B**), and Elovl6 with Pnpla3 (**C**) were determined by immunoblotting after immunoprecipitation (IP) using the indicated antibodies.

Supporting Figure 9. Liver histology, hepatic lipid contents, and hepatic FA composition of Flox, *ob/ob*, and *ob/ob*-LKO mice, and the impact of Elovl6 deletion on hepatic insulin signaling

(**A**) H&E staining of liver sections from representative mice from each group. Scale bar = 100 μm. (**B**) Hepatic TAG and T-Cho levels in 12-week-old Flox, *ob/ob*, and *ob/ob*-LKO mice (n = 5 or 6 mice per group). (**C**) Plasma ALT levels in in 12-week-old Flox, *ob/ob*, and *ob/ob*-LKO mice (n = 10–17 mice per group). (**D**) Hepatic FA composition in Flox, *ob/ob*, and *ob/ob*-LKO mice (n = 5 mice per group). **p < 0.01, ***p < 0.001. (**E**) Proposed models of hepatic insulin signaling for Flox and LKO mice.

Figure for Reviewers

(**A**) Expression of tumor necrosis factor α (*Tnfa*), interleukin 6 (*Il6*), serum amyloid A 1 (*Saa1*), and serum amyloid A 2 (*Saa2*) in liver from Flox and LKO mice fed either a chow or HSD (n = 11−18 per group). (**B**) Expression of *Tnfa*, *Il6*, *Saa1*, and *Saa2* in liver from HSD-fed Flox and LKO mice infected with either Ad-GFP or Ad-Pnpla3 (n = 8−14 per group). (**C**) Expression of *Tnfa*, *Il6*, *F4/80*, chemokine (C-C motif) ligand 2 (*Ccl2*), *Saa1*, and *Saa2* in liver from Flox, ob/ob, and ob/ob-LKO mice (n = 8−14 per group). Results are expressed as mean ± SEM. *p < 0.05, **p < 0.01, ***p < 0.001.
