Effect of acupuncture on salivary immunoglobulin A after a bout of intense exercise

Yuichi Matsubara,1 Kazuhiro Shimizu,1,2 Yuko Tanimura,1 Toshikazu Miyamoto,1 Takayuki Akimoto,3,4 Ichiro Kono1

ABSTRACT
In the field of athletics, acupuncture has been used for treatment of injury, reduction of fatigue and management of physical condition. However, there is little information on the effect of acupuncture on the immune function in response to exercise.

Purpose The aim of this study was to examine the effect of acupuncture treatment on the mucosal immune function after a single period of intense exercise by measuring salivary immunoglobulin A (SIgA).

Methods 12 healthy men (23.6±0.3 years) participated in this study with a crossover design. The subjects exercised on a bicycle equipped with an ergometer at 75% VO2max for 60 min. Acupuncture treatment was applied at LU6, LI4, ST36 and ST6, for 30 min after the exercise. The control treatment was rest without acupuncture and that the order of the treatment was randomised. We measured parameters including saliva flow rate, SIgA concentration, SIgA secretion rate, heart rate and plasma catecholamine concentration all before the exercise and at 1 h, 2 h, 3 h, 4 h and 24 h after the exercise. The visual analogue scale for self-perceived tiredness and the profile of mood states questionnaires were recorded before the exercise and at 24 h after the exercise.

Result Intense exercise-induced decrease of SIgA levels was attenuated by the acupuncture treatment. In contrast, the subjective fatigue score and psychological measurement were not affected by the acupuncture.

Conclusion Acupuncture treatment may attenuate the decrease in SIgA level induced by intense exercise.

INTRODUCTION
Athletes have to maintain and even improve high-fitness levels and skills to perform well at competitions. Therefore, they need to do high-frequency, high-intensity training. Among elite athletes and coaches it is well known that athletes have a higher risk of upper respiratory tract infection (URTIs) than non-athletes.1 It has been reported that acute high-intensity exercise and long-term heavy training lead to a decrease in immune functions.2–3 Additionally, Nieman has reported that people who habitually do moderate exercise have less risk of URTI than those people who do not; however, he also has reported that high-intensity exercise increases the risk of URTI.4 Since it is known that URTI adversely affects training and performance,5 it is important for athletes to avoid URTI in order to maintain a good physical and mental condition.6–9

Several studies have shown that suppression of salivary immunoglobulin A (SIgA) level in elite athletes frequently results in URTI.1011 SIgA, which is the predominant immunoglobulin in secretions of the mucosal immune system, penetrates the body through the mucosal tissues,1213 neutralises various toxins and viruses, and inhibits the attachment and replication of pathogenic microorganisms.1314

Acupuncture is used most commonly as an adjunctive treatment for the relief of chronic or acute pain. Acupuncture treatment is also a very common method for modulating the physical condition of various athletes.15 In athletics, acupuncture is most widely used to treat pain associated with musculoskeletal injuries, but it has also been used to treat physical conditions, such as relieving pain and tiredness, and promote regeneration of injured areas of the body. Furthermore, it has been reported that acupuncture treatment is effective for soothing tight muscles, improving peripheral blood circulation, increasing the pain threshold and adjusting the autonomic nervous system.16–18 Acupuncture also has been recognised to increase ‘natural healing power,’ including immunological responses that can improve the physical and mental condition and even can cure and prevent diseases.19

Although acupuncture treatment is considered to adjust the immune function and contribute to the stabilisation of human homeostasis,20 few studies have been conducted to determine the combined effects of acupuncture treatment and exercise on the human immune function. So far, our group has published only one study investigating the effect of acupuncture treatment on the immune function of athletes during competition.21 We reported that continuous acupuncture treatment counteracted intense training-induced decrease in SIgA and also had positive effects on physical and mental conditions. This study was the first to demonstrate that acupuncture treatment attenuated the reduction in the mucosal immune function of athletes during competition.22 Since this study was conducted during a period of sports competition, it could serve as a basic experiment for a new study, one that investigates the capability of acupuncture treatment to attenuate both the acute intense exercise-induced decrease in SIgA and the reduction in the mucosal immune function in athletes. The only conceptual change necessary in the experiment would be to omit the factors other than acupuncture treatment that affect SIgA levels.

The purpose of this study was to examine the effect of acupuncture treatment on the mucosal immune function after acute high-intensity exercise by measuring salivary SIgA levels. We hypothesised that acupuncture treatment would lessen the decrease of SIgA induced by the exercise.
VO2max. Subjects then underwent a submaximal cycle exercise (1) increased workload without corresponding increase in VO2; criteria for maximal effort included at least two of the following: loads increased by 30 W every 3 min until exhaustion. Objective increased to 60, 80 and 100 W for 2 min. Subsequently, the work-

alating and subsequent incremental exercise. The workload was monitored on a cycle ergometor (AE280S; Minato Medical Science, Osaka, Japan). The protocol consisted of 2 min of unloaded ped-

aling and repeated every 30 s. The maximal O2 uptake over a 30 s period was defined as VO2max. Subjects then underwent a submaximal cycle exercise test. The workload was increased to 60, 80 and 100 W for 2 min. Subsequently, the work-

loads increased by 30 W every 3 min until exhaustion. Objective criteria for maximal effort included at least two of the following: (1) increased workload without corresponding increase in VO2; (2) respiratory exchange quotient equal to or greater than 1.10; (3) pedal cadence less than 50 rpm in spite of maximal voluntary effort. The highest O2 uptake over a 30 s period was defined as VO2max. Subjects then underwent a submaximal cycle exercise test. The tests were taken within 1 week of the VO2max test, at least 4 d apart. In the submaximal cycle exercise test, subjects exercised on a cycle ergometer for 1 h at 75% of their VO2max.

Heart rates
The heart rates of the subjects were measured at the same points of sample collections. The heart rate was measured by Polar S610 (Polar, Kempele, Finland).

Subjective evaluations of physical and mental conditions
Subjective evaluations of subject conditions were made during the experiment. The visual analogue scale for self-perceived tiredness was used at the same points as sample collections. This rating was assessed using a 100 mm continuous scale. In addition, a Japanese version of the profile of mood state (POMS) questionnaire was administered to assess the subjective mental states before the exercise test and after 24 h. Six mood states are used in POMS:

Table 1 Subjects’ characteristics

| Number | 12 |

| Body fat (%) | 16.2±1.1 |
| Maximal oxygen uptake (ml/kg/min) | 41.6±1.6 |

Date were expressed mean±SE

METHODS
Subjects
Twelve healthy sedentary men (23.6±0.3 years) were recruited from a collegiate population to participate in this study (table 1). None of subjects reported a history of smoking. All subjects were provided verbal and written information about the purpose, measures and ethical considerations of the experiment before their informed written consent was obtained. This study was approved by the Ethical Committees of the Institute of Health and Sport Sciences and the Institute of Clinical Medicine of University of Tsukuba; it also was determined that the study conformed to the principles outlined in the Declaration of Helsinki. The subjects were randomly distributed into two groups and with crossover design. The experiment was divided into two phases, each beginning with a submaximal cycle exercise test. In the first phase, one group received acupuncture treatment while the other rested, and within a week, in the second phase, the group roles were reversed.

Exercise test
Maximal oxygen uptake (VO2max) of the subjects was deter-

mined through the use of an incremental bicycle exercise test. The subjects rode the bicycle to exhaustion, and their breath-by-

breath oxygen uptake and carbon dioxide production were mon-

itored through the use of an incremental bicycle exercise test. The subjects rinsed their mouths for 30 sec 3 times with 100 ml of mineral water, and then rested for at least 5 min. Saliva produ-

ction was stimulated by the chewing of sterilised cotton (Salivate; Saersted, Vümbrucht, Germany) for 2 min at a frequency of 1 chew/sec. Saliva was separated from the cotton swab by centrifugation at 3000 rpm for 15 min. The amount of saliva in grammes was converted to millilitres based on an assumed saliva density of 1 g/ml, as described in one of our previous studies. After the sample volume was measured, samples were frozen at −80°C and stored until analysis.

Saliva collection
Saliva samples were collected at rest before exercise (pre), imme-

diately after exercise (P0), 1, 2, 3 and 4 h after exercise (P1, P2, P3, P4), and 24 h after exercise (P24), as described in our previous studies. The subjects were free to drink water during the experiment. Light meals were given to all the subjects at the sample collection, which was taken within 1 h after the exercise. The subjects rinsed their mouths for 30 sec 3 times with 100 ml of mineral water, and then rested for at least 5 min. Saliva produ-

duction was stimulated by the chewing of sterilised cotton (Salivate; Saersted, Vümbrucht, Germany) for 2 min at a frequency of 1 chew/sec. Saliva was separated from the cotton swab by centrifugation at 3000 rpm for 15 min. The amount of saliva in grammes was converted to millilitres based on an assumed saliva density of 1 g/ml, as described in one of our previous studies. After the sample volume was measured, samples were frozen at −80°C and stored until analysis.

S IgA measurement
S IgA concentrations were measured by enzyme-linked immuno-

sorbent assay, according to the procedures of our previous study. Rabbit antihuman secretory component IgG fraction (MBL, Nagoya, Japan) with coating buffer was added to each well of a microtitre plate (IMMULON-2, Dynex Technologies, Chantilly, VA) and kept at 4°C for more than 8 h. After 250 μl of phosphate-buffered saline (PBS) containing 1% bovine serum albumin (BSA, Sigma, St Louis, MO) was added, the wells were blocked for 2 h at normal room temperature. Saliva samples were thawed, centrifuged at 10 000 rpm for 5 min, diluted with 100 μl of PBS containing 1% BSA and incubated for 1 h. By using purified human S IgA (MP Biomedicals, Inc, Santa Ana, CA), known concentrations of S IgA were also plated to establish standard values. After the plate was washed with PBS-Tween, goat Fab/anti-lgA conjugated with horse radish peroxide HRP (man-

rose binding lectin) was added to the plate and incubated for 1 h. After washing, substrate solution was added, and the colour intensity produced after 10 min was measured by a microplate reader (Model550, Bio Rad, Hercules, CA) at 490 nm wave length. For analysis of the S IgA levels, data were expressed as the S IgA secretion rate (μg/min). This rate was calculated by

Original paper
multiplying the absolute SlgA concentration (μg/ml) by the saliva flow rate (ml/min), which was calculated by dividing the total volume of saliva obtained in each sample (ml) by the time taken to produce the sample (min).

**Blood collection and measurement of plasma catecholamine concentrations**

Blood samples were collected at the same times as saliva collections. Blood was sampled from the antecubital vein in the arm. Plasma was generated by centrifuging blood at 3000 rpm for 15 min at 4°C; it was frozen at −80°C until the analysis of catecholamine concentrations. Plasma concentrations of epinephrine and norepinephrine were measured by an automatic catecholamine analyser (HLC-725CA II, Tosoh, Tokyo, Japan).

**Statistical analysis**

All data were represented as mean±SE. The effect of acupuncture treatment was determined by using two-way analyses of variance with repeated measures. A Tukey-Kramer adjustment was applied to the posthoc test. The significance level of all statistical analyses was set at p<0.05.

**RESULTS**

**Salivary SlgA levels**

As shown in figure 1, the SlgA secretion rate significantly decreased from P0 to P3 in the control group (p<0.05) but did not decrease significantly in the acupuncture group. In contrast, the SlgA of the acupuncture group significantly increased at P24. The SlgA secretion rate was significantly higher in the acupuncture group than in the control group at P1 and P24 (p<0.05). The concentration of SlgA significantly decreased from P0 to P3 in the control group (p<0.05) and decreased significantly only at P2 in the acupuncture group (figure 2).

**Figure 1  Temporal change in salivary immunoglobulin A (SlgA) secretion rate after exercise. Two-way analyses of variance (acupuncture–time) showed significant treatment effects in improving the levels of SlgA (p=0.0017). At P24, the SlgA secretion rate of the acupuncture group increased significantly. In the control group, the SlgA secretion rate significantly decreased from P0 to P3. Data were expressed as mean±SE; *p<0.05 (vs pre), †p<0.05 between groups.**

**Figure 2  Temporal change in salivary immunoglobulin A (SlgA) concentration after exercise. Two-way analyses of variance (acupuncture–time) showed no significant treatment effects in improving the concentrations of SlgA (p=0.2647). However, there was a significant main effect of time for SlgA concentration (p<0.001). In the acupuncture group, the SlgA concentration decreased significantly only at P2. In the control group, the SlgA concentration significantly decreased from P0 to P3. Data were expressed as mean±SE; *p<0.05 (vs pre).**

**Saliva flow rates**

Figure 3 shows that the saliva flow rate did not significantly change in the control group. In contrast, the saliva flow rate of the acupuncture group significantly increased at P1 and P24 (p<0.05). The saliva flow rate was significantly higher in the acupuncture group than in the control group at P1 and P24 (p<0.05).

**Figure 3  Temporal change in saliva flow rate after exercise. Two-way analyses of variance (acupuncture–time) showed significant treatment effects in increasing the saliva flow (p=0.002). In the acupuncture group, the saliva flow rate significantly increased at P1 and P24. In the control group, the saliva flow rate did not significantly change during the study. Data were expressed as mean±SE; *p<0.05 (vs pre), †p<0.05 between groups.**

**Plasma catecholamine concentrations**

As shown in table 2, the epinephrine concentration increased at P0 and P1 in the control group. In contrast, the epinephrine concentration of the acupuncture group increased at P0. The norepi-
Acupuncture causes decrease of SIgA levels and increases the risk of URTI.\textsuperscript{10, 11} It also has been reported that reduction in SIgA levels might increase the risk of URTI.\textsuperscript{30, 31} It has been reported that the autonomic nervous system reaction relate to central nerve system which stimulated by acupuncture.\textsuperscript{33, 34} This means that stimulating the sympathetic nerve, the parasympathetic nerve, or both nerves by acupuncture treatment could promote SlgA secretion. In this study, besides saliva, epinephrine, norepinephrine and heart rate, which are related to the autonomic nervous system, were measured. In the acupuncture group, the saliva flow rate increased at P1 and P24 but did not change in the control group throughout the study. On the other hand, the acupuncture treatment did not affect the whole autonomic nervous system, but only affected a part of it after intensive exercise. Therefore, it is possible that acupuncture treatment might improve SlgA secretion by stimulating the autonomic nervous system.

In this study, acute high-intensity exercise decreased SlgA levels, but then acupuncture treatment increased SlgA levels. However, the acupuncture treatment had no effect on the self-perceived tiredness resulting from the acute high-intensity exercise. There also were no effects on the POMS score in the acupuncture group. On the other hand, several studies have reported that acupuncture treatment promoted relief from muscle tension and tiredness among athletes.\textsuperscript{21, 35} It was possible that acupuncture treatment affected the autonomic nervous system.\textsuperscript{16, 17} Moreover, it has been reported that the autonomic nervous system reaction to central nerve system which stimulated by acupuncture.\textsuperscript{33, 34} This means that stimulating the sympathetic nerve, the parasympathetic nerve, or both nerves by acupuncture treatment could promote SlgA secretion. In this study, besides saliva, epinephrine, norepinephrine and heart rate, which are related to the autonomic nervous system, were measured. In the acupuncture group, the saliva flow rate increased at P1 and P24 but did not change in the control group throughout the study. On the other hand, the acupuncture treatment did not affect the whole autonomic nervous system, but only affected a part of it after intensive exercise. Therefore, it is possible that acupuncture treatment might improve SlgA secretion by stimulating the autonomic nervous system.

neuropeptide concentration increased at P0 and P2 in the control group. In contrast, the norepinephrine concentration of the acupuncture group increased at P0, P2 and P3.

**Heart rates**

Table 3 shows that the heart rate increased from P0 to P3 in the control group. In contrast, the heart rate of the acupuncture group increased from P0 to P4.

**Subjective evaluations of physical and mental conditions**

The visual analogue scale score on fatigue increased for both groups at P0 but returned to baseline after P0. All the mood states except ‘vigour’ at P24 in both groups were lower than they were at pre. However, there were no significant differences between the groups on any items.

**DISCUSSION**

In the present study, we provided evidence that acupuncture treatment positively affects SlgA levels and saliva flow rates in healthy sedentary male subjects after a single bout of intense exercise. This result suggests that acupuncture treatment works on the autonomic nervous system and may improve mucosal immune protection.

SlgA has the important function of blocking entrance of pathogenic organisms and preventing infections. It has been reported that reduction in SlgA levels might increase the risk of URTI.\textsuperscript{10, 30, 31} It also has been reported that intensive exercise causes decrease of SlgA levels and increases the risk of URTI.\textsuperscript{10, 11}

In the present study, we showed that acute highly intense exercise reduced SlgA levels, specifically that acupuncture treatment increased SlgA levels and promoted recovery. This suggests that acupuncture treatment could be very effective in improving SlgA levels, reducing URTI, and maintaining better physical condition.

Secretion from the salivary glands is controlled by both the sympathetic and parasympathetic nervous systems.\textsuperscript{32} When the sympathetic nerve activity is dominant, small amounts of viscous saliva is secreted; when parasympathetic nerve activity is dominant, watery serous saliva is secreted.\textsuperscript{32} The mechanisms underlying the effects of acupuncture treatment still remain to be clarified, but many studies have shown that acupuncture treatment affected the autonomic nervous system.\textsuperscript{16, 17} Moreover, it has been reported that the autonomic nervous system reaction to central nerve system which stimulated by acupuncture.\textsuperscript{33, 34} This means that stimulating the sympathetic nerve, the parasympathetic nerve, or both nerves by acupuncture treatment could promote SlgA secretion. In this study, besides saliva, epinephrine, norepinephrine and heart rate, which are related to the autonomic nervous system, were measured. In the acupuncture group, the saliva flow rate increased at P1 and P24 but did not change in the control group throughout the study. On the other hand, the acupuncture treatment did not affect the whole autonomic nervous system, but only affected a part of it after intensive exercise. Therefore, it is possible that acupuncture treatment might improve SlgA secretion by stimulating the autonomic nervous system.

In this study, acute high-intensity exercise decreased SlgA levels, but then acupuncture treatment increased SlgA levels. However, the acupuncture treatment had no effect on the self-perceived tiredness resulting from the acute high-intensity exercise. There also were no effects on the POMS score in the acupuncture group. On the other hand, several studies have reported that acupuncture treatment promoted relief from muscle tension and tiredness among athletes.\textsuperscript{21, 35} It was possible that the subjects in this study did not receive continuous mental and physical stresses. It must be remembered, though, that SlgA levels were decreased even though the subjects were not aware of either mental or physical stress. The difference between subjective feelings and actual mucosal immune function might indicate one of the factors that cause the physical condition of athletes to deteriorate. These results suggest that the acupuncture treatment had little placebo influence on the subjects, because the subjective index did not change during the experiment.

It has been shown that acupuncture treatment restores the balance of the body’s function.\textsuperscript{36} In addition, in actual acupuncture treatment, specific acupuncture points are selected based on each patient’s individual conditions. In our study, the same acupuncture points were selected and the same treatments were given to...
all subjects, in order to keep all experimental conditions equal. Furthermore, the acupuncture treatment given in our study was physical stimulation by a needle, which might have a little different effect from that of a typical acupuncture treatment in clinics.

There is a need in the future to validate how effective acupuncture treatment is for decreasing URTI risks, by examining the relation between the influence of acupuncture treatment on S IgA levels and the incidence of URTI during a period of sports competition. There also is a need to determine whether the effect of acupuncture was point specific in this study and whether electrical stimulation is necessary in the future. Once all the tasks mentioned above have been completed successfully, it is conceivable that acupuncture could be widely recognized as an effective treatment to keep athletes from getting URTI by adjusting their immune systems and even help athletes with their self-conditioning.

Summary

► Salivary immunoglobulin levels fall in athletes after a bout of exercise.
► Acupuncture immediately after exercise partially reverses this effect.
