Fbw7 α Regulates Liver Triglyceride via KLF5/PPAR γ 2

Abstract

F-box and WD repeat domain-containing 7 α (Fbw7 α) is the substrate recognition component of a ubiquitin ligase that controls the degradation of factors involved in cellular growth, including c-Myc, cyclin E, and c-Jun. In addition, Fbw7 α degrades the nuclear form of sterol regulatory element binding protein (SREBP)-1a, a global regulator of lipid synthesis, particularly during mitosis in cultured cells. This study investigated the *in vivo* role of Fbw7 α in hepatic lipid metabolism. siRNA knockdown of Fbw7 α in mice caused marked hepatosteatosis with the accumulation of triglycerides (TGs). However, inhibition of Fbw7 α did not change the level of nuclear SREBP-1 protein or the expression of genes involved in fatty acid synthesis and oxidation. *In vivo* experiments on the gain and loss of Fbw7 α function indicated that Fbw7 α regulated the expression of peroxisome proliferator-activated receptor (PPAR) γ 2 and its target genes involved in fatty acid uptake and triglyceride synthesis. These genes included fatty acid transporter CD36, diacylglycerol acyltransferase 1 (DGAT1), and fat-specific protein 27 (Fsp27). The regulation of PPAR γ 2 by Fbw7 α was mediated, at least in part, by the direct degradation of the Krüppel-like factor 5 (KLF5) protein, upstream of PPAR γ 2 expression. Hepatic

Fbw7 α contributes to normal fatty acid and triglyceride metabolism, functions which represent novel aspects of this cell growth regulator.

Introduction

F-box and WD repeat domain-containing 7 (Fbw7) is the component of an evolutionary conserved complex of the Skp1-Cul1-F-box protein ubiquitin ligase (SCF) and is involved in substrate recognition of the complex (1,2). Fbw7 targets several proto-oncogenes that function in cell growth and division pathways, including c-Myc, cyclin E, Notch, and c-Jun (3-7). Fbw7, is perturbed in many human malignancies and is an established tumor suppressor (8-11). Mouse Fbw7 exists in three different isoforms: α , β , and γ . The α isoform is expressed ubiquitously, whereas the β and γ isoforms are restrictedly expressed in the brain, heart, testis, and skeletal muscle (12). Intriguing characteristics of Fbw7 α have recently been described by Ericsson et al. who demonstrated that this cell growth regulator also regulated the degradation of the nuclear forms of the sterol regulatory element binding protein (SREBP) family (13,14).

SREBPs, belonging to the bHLH-Zip transcription factor family, are established regulators of lipid synthesis. The unique features

Fbw7 α Regulates Liver Triglyceride via KLF5/PPAR γ 2

of SREBPs are their rER membrane-bound transcription factors. These factors need to undergo proteolytic cleavage for nuclear transport to activate the expression of genes involved in lipid synthesis. This represents the crucial step for sterol and fatty acid synthetic gene regulation (15-17). The SREBP family includes three isoforms: SREBP-1a, -1c, and -2 (18-20). SREBP-2 governs cellular sterol regulation, whereas hepatic SREBP-1c controls fatty acid and triglyceride synthesis depending on the nutritional state of the liver. SREBP-1a is highly expressed in growing cells and contributes to the synthesis of cholesterol, triglyceride (TG), and phospholipid for the supply of membrane lipids during cell growth (21,22). Nuclear SREBP-1a regulates the cell cycle and growth by itself, indicating its strong association with cell growth (23,24).

Without a proteasome inhibitor such as calpain inhibitor I in cell cultures, nuclear SREBPs are rapidly degraded by the ubiquitin–proteasome pathway after cleavage. Recently, Fbw7 was reported to be the key factor for this degradation of SREBPs in cultured cells (14). SREBP-1a is phosphorylated at several sites depending on the cell cycle and then degraded by the ubiquitin–proteasome system. During mitosis, nuclear SREBP-1a is stabilized, and it activates lipid synthesis to supply membrane lipids (25). Thus, Fbw7 controls the degradation of SREBPs

in cultured cells in relation to the cell cycle and growth. However, its physiological roles *in vivo* are yet to be determined. In the present study, the effects of Fbw7 α modification on SREBPs and lipid metabolism in the liver were investigated.

Experimental procedures

Materials - Antibodies to phosphorylated c-Jun (Ser63) and Lamin A/C were obtained from Cell Signaling Technology (Beverly, MA USA); antibodies to SREBP-1, c-Jun, Krüppel-like factor 5 (KLF5), and α -tubulin were obtained from Santa Cruz Biotechnology (Santa Cruz, CA USA), and that to Fbw7/hCdc4 was purchased from Abcam (Tokyo, Japan).

N-acetyl-Leu-Leu-norleucinal-CHO (ALLN; calpain inhibitor I) and fenofibrate were purchased from Sigma (St. Louis, MO USA), redivue [α -³²P]dCTP from GE Healthcare UK Ltd. (Buckinghamshire, England), and [1-¹⁴C]palmitate from PerkinElmer Life Sciences (Waltham, MA USA). Restriction enzymes were obtained from Takara Bio Inc. (Shiga, Japan), and plasmid DNAs for transfection were prepared using the Qiagen Plasmid Midi Kit (Qiagen, Hilden, Germany).

Animal experiments - All animal studies were approved by the Animal Care Committee of the University of Tsukuba. Male C57BL/6J mice (9-

Fbw7 α Regulates Liver Triglyceride via KLF5/PPAR γ 2

and 14-week-old) were purchased from Clea (Tokyo, Japan), and male B6.V-*Lep*^{ob}/J (ob/ob) mice (7-week-old) were obtained from Charles River (Kanagawa, Japan). SREBP transgenic mice (13-week-old) overexpressing the active form of human SREBP-1c under the control of the rat phosphoenolpyruvate carboxykinase (PEPCK) promoter (SREBP1c-Tg) were generated as described previously (26). In addition, SREBP-1 knockout mice (SREBP1-KO) (6–8-week-old) were generated as described previously (27). KLF5 flox mice, in which the second exon was flanked by two lox sites, were also prepared and established (Ema M, manuscript in preparation). The mice were housed in colony cages, maintained on a 12-h light/12-h dark cycle, given free access to water and standard chow diet (Oriental Yeast, Tokyo, Japan); the mice were adapted to their new environment for at least one week prior to the experiments. After the adenovirus injection, the mice were housed during the periods indicated and then sacrificed in the non-fasted state. Tissues were isolated immediately, weighed, and stored in liquid nitrogen. Plasma metabolic parameters were measured by using commercial kits according to the manufacturer's instructions (all test kits were obtained from Wako Pure Chemical Industries, Osaka, Japan).

Preparation of recombinant adenovirus - We

subcloned Fbw7-specific RNAi constructs using the Fbw7 coding sequence 5'-GCTGAAACTGGAGAGTGTA-3' into a U6 entry vector (Invitrogen, Carlsbad, CA USA). We then generated the recombinant adenoviral plasmid by homologous recombination with a pAd promoterless vector (Invitrogen). Next, we subcloned peroxisome proliferator-activated receptor (PPAR) γ 2-specific RNAi constructs using the PPAR γ 2 coding sequence 5'-GCCTATGAGCACTTCACAA-3' and generated the recombinant adenoviral plasmid as described above. We subcloned hemagglutinin-tagged mouse Fbw7 α cDNA into the pENTR4 vector (Invitrogen) and generated a recombinant adenoviral plasmid by homologous recombination with a pAd/CMV/V5-DEST vector (Invitrogen). We produced recombinant adenoviruses in HEK-293 cells and purified them by CsCl gradient centrifugation, as described previously (28,29). The recombinant adenovirus expressing the Cre recombinase AxCANCre was produced by Dr. Izumu Saito (Institute of Medical Science, University of Tokyo, Japan) and was obtained from Riken DNA Bank (Tsukuba, Japan).

RNA extraction, northern blot analysis, and quantitative real-time PCR - Total RNA was isolated from mouse livers and primary hepatocytes using the Sepazol RNA I Super

Fbw7 α Regulates Liver Triglyceride via KLF5/PPAR γ 2

reagent (Nacalai Tesque Inc., Kyoto, Japan). Northern blot analysis was performed using the indicated 32 P-labeled probe, as described previously (28,30). First-strand cDNA was synthesized using a High Capacity cDNA Reverse Transcription Kit (Applied Biosystems, Foster City, CA USA), and comparative analysis of mRNA levels was performed using fluorescence-based real-time PCR. Real-time PCR analyses were performed using the ABI 7300 PCR system (Applied Biosystems). Quantification of fat-specific protein 27 (Fsp27) was performed using a Taqman gene expression assay (Applied Biosystems), while quantification of other genes was performed using the SYBR-Green Dye (Nippon Gene, Tokyo, Japan). The relative abundance of each transcript was calculated using a standard curve of cycle thresholds for serial dilutions of a cDNA sample and then normalized to cyclophilin levels (31). The expression levels of cyclophilin used as an internal control in each experiment were not affected by procedures such as siRNA transfection. Primer sequences are described in Supplementary Table S1.

Measurement of metabolic parameters - We measured the plasma levels of glucose, insulin, non-esterified fatty acid (NEFA), TG, total cholesterol (TC), aspartate aminotransferase (AST), and alanine aminotransferase (ALT) as well as the levels of TG and TC in the liver, as

described previously (32).

Expression plasmids - The expression plasmid for the human nuclear form of SREBP-1c has been described previously (33). Expression plasmids encoding mouse Fbw7 α and KLF5 were generated by PCR amplification, followed by the insertion of cDNAs into pcDNA3.1(+) (Promega). The following primers were used: Fbw7 α , 5'-primer 5'-CTTAAGCTTGCCACCATGAATCAGGAAC TGCTCTCTGT-3', 3'-primer 5'-CCGGAATTCTCATTTCATGTCCACATCA AAGTCCAG-3' and KLF5, 5'-primer 5'-CTTAAGCTTGCCACCATGCCCACGCGGG TGC-3', 3'-primer 5'-CCGGAATTCTCAGTTCTGGTGGCGCT-3'. Restriction sites *Hind*III and *Eco*RI were added to each 5'-primer and 3'-primer, respectively. PCR products were digested with *Hind*III and *Eco*RI, and then inserted into the respective sites of pcDNA3.1(+). Ligation was performed using a Quick Ligation Kit (New England Biolabs Inc., Ipswich, MA USA).

Cell cultures - Cos-7 cells were cultured in DMEM (Sigma) supplemented with 5% FBS and 1% penicillin–streptomycin (Sigma). For the KLF5 degradation assay, Cos-7 cells were seeded 24 h before transfection in 6-cm plates at a density of 3×10^5 cells/plate. Mouse primary hepatocytes were isolated from male C57BL/6J mice, as described previously (28) and seeded in 10-cm

Fbw7 α Regulates Liver Triglyceride via KLF5/PPAR γ 2

plates for adenovirus infection and measurement of palmitate uptake.

Cellular uptake of [1-¹⁴C]palmitate - [1-¹⁴C]palmitate uptake by primary hepatocytes was measured as described previously, but with some modifications (34). Briefly, the isolated hepatocytes were infected with adenovirus for 60 h and incubated for 3 h in a culture medium containing 200 μ M palmitate, radiolabeled [1-¹⁴C]palmitate (0.1 μ Ci/ml), 2 μ M insulin, and 1% BSA (Sigma). After the 3-h incubation, the cells were washed twice with ice-cold PBS and then scraped into it. Cellular lipids were extracted with chloroform/methanol as described by Bligh and Dyer (35), and the residual radioactivity of each sample was then determined.

KLF5 degradation assay - Each indicated expression plasmid (3 μ g) was transfected into Cos-7 cells using the FuGENE 6 reagent (Roche Applied Science, Basel, Switzerland), according to the manufacturer's instructions. After 36 h of transfection, the cells were treated with cycloheximide (100 μ g/mL) to stop protein synthesis and then incubated with or without ALLN for the indicated times.

Immunoblot analysis - We performed an immunoblot analysis using the antibodies indicated as described previously (29,36,37). The intensity of each detected band was quantified using the image processing software ImageJ

(National Institute of Mental Health, Bethesda, MD USA).

Liver histology - Mouse livers were fixed in 10% neutral buffered formalin and embedded in paraffin. The sections were subjected to standard hematoxylin and eosin staining.

Statistical analyses - All data are expressed as mean \pm standard error of the mean (SEM). Statistical analyses were performed using unpaired Student's *t*-test, one sample *t*-test, or two-way ANOVA, followed by Tukey's procedure.

Results

To estimate the contribution of Fbw7 to the physiological regulation of hepatic SREBP-1c and hepatic lipogenesis, Fbw7 was knocked down in murine livers by intravenous injection of adenovirus producing Fbw7 siRNA (Fbw7i). We confirmed that only the Fbw7 α isoform was expressed in murine livers and cultured hepatoma cells, and Fbw7i fully suppressed Fbw7 α expression in cultured hepatoma cells, as estimated by quantitative real-time PCR (data not shown). In livers of mice infected with Fbw7i, the decrease in Fbw7 α level was approximately 70% (Figure 1A). This hepatic Fbw7 knockdown caused fatty liver and a slight, but significant, enlargement of the liver (Figures 1B and 1C).

Fbw7 α Regulates Liver Triglyceride via KLF5/PPAR γ 2

These mice exhibited no significant changes in food intake, white adipose tissue weight, or body weight compared to animals infected with adenovirus producing LacZ siRNA (LacZi) as a control (Figure 1D and data not shown). Of the plasma metabolic parameters, TG, glucose, and insulin levels were reduced significantly by infection with Fbw7i (Table 1). These data indicated that fatty liver was not likely to be associated with overnutrition or obesity. Hepatosteatosis was confirmed by liver histology (Figure 1E) with a marked increase in the liver content of TG (Figure 1F), but not TC (Figure 1G).

Immunoblot analysis of hepatic nuclear extracts demonstrated that the increase in nuclear SREBP-1 protein by Fbw7 knockdown was minimal whereas c-Jun protein, another target of Fbw7, accumulated markedly without a change in its mRNA level (Figures 2A and 2B). This finding confirmed Fbw7 inactivation. The precursor form of SREBP-1c in the whole cell fraction did not change noticeably. Lack of hepatic SREBP-1 activation by Fbw7 α suppression was confirmed by the gene expression pattern estimated by real-time PCR (Figure 2C). With the exception of stearoyl-CoA desaturase 1 (SCD1), mRNA levels of SREBP-1c and SREBP-1 target genes involved in fatty acid synthesis such as acetyl-CoA carboxylase, fatty

acid synthase (FAS), and long chain fatty acid elongase 6 (Elovl6) were not up-regulated. There were no changes in the expression of carbohydrate response element binding protein, another transcription factor that controls fatty acid synthesis (Figure 2C). The mRNA levels of PPAR α , a crucial regulator of hepatic fatty acid oxidation enzymes, and the PPAR α target genes acyl-CoA oxidase and medium chain acyl-CoA dehydrogenase did not change (Figure 2D). In contrast, hepatic expression of PPAR γ 2 increased significantly by Fbw7 knockdown, while expression of PPAR γ 1 increased minimally. Consistent with these findings, the expression of aP2, another PPAR γ 2 target gene, was also up-regulated (Figure 2E). We observed marked increases in the mRNA levels of CD36, a transporter involved in the hepatic uptake of plasma fatty acids, mitochondrial glycerol-3-phosphate acyltransferase (GPAT), and diacylglycerol acyltransferase 1 (DGAT1), an enzyme in TG synthesis (Figure 2F). Fsp27/CIDE-C, a lipid droplet binding protein known to promote lipid accumulation in adipocytes, has recently been reported to contribute to hepatosteatosis as a PPAR γ target (38-40). Furthermore, the expression of Fsp27 was enhanced by Fbw7 knockdown (Figure 2F). These data indicated that fatty liver induced by Fbw7 knockdown was caused by an elevation in

Fbw7 α Regulates Liver Triglyceride via KLF5/PPAR γ 2

fatty acid uptake, TG synthesis, and lipid accumulation, rather than by an increase in *de novo* fatty acid synthesis or a decrease in fatty acid degradation. These genes involved in the accumulation of TG are direct targets of PPAR γ 2. Consistent with the liver cholesterol content remaining unchanged, SREBP-2 target genes involved in cholesterol metabolism such as low density lipoprotein receptor (LDLR) and HMG-CoA reductase (HMGCR) did not change with Fbw7 knockdown (Figure 3A). Apolipoprotein B and microsomal triglyceride transfer protein involved in TG secretion did not decrease (Figure 3B). Expression of gluconeogenic genes such as PEPCK, glucose-6-phosphatase, and glucose transporter 2 did not change, while glucokinase expression decreased significantly by Fbw7 knockdown (Figure 3C). Phosphorylated protein levels of c-Jun increased by Fbw7 knockdown (Figure 2A). Expression of cytokines such as IL-1 β and IL-6 did not change (Figure 3D).

The possibility that SREBP-1 did not contribute to fatty liver induced by Fbw7 knockdown was investigated further in SREBP1-KO. Littermates and SREBP1-KO had similar basal mRNA levels of Fbw7 α (Figure 4A). After Fbw7 knockdown, the TG content of SREBP1-KO livers increased to levels comparable to littermates (Figure 4B). Inhibition of Fbw7 function by knockdown was

confirmed by the increased levels of c-Jun and phosphorylated c-Jun proteins in nuclear extracts (Figure 4C). Lipogenic enzyme genes such as FAS and SCD1 were not affected by Fbw7 knockdown in SREBP1-KO livers (Figure 4D). Fbw7 knockdown did not alter HMGCR expression or liver cholesterol content (Figure 4E and data not shown). Meanwhile, PPAR γ 2 and CD36 were up-regulated by Fbw7 knockdown irrespective of the presence or absence of SREBP-1 (Figure 4F), indicating SREBP-1c-independent and PPAR γ 2-mediated TG accumulation.

Besides its stability in the nucleus, nuclear SREBP-1c protein level is regulated mainly by its mRNA level and cleavage activity of the precursor SREBP-1c protein for nuclear transport. To exclude the possibility that the lack of change in the nuclear SREBP-1 protein by Fbw7 knockdown was attributable to changes in mRNA expression and cleavage activity of the precursor protein, we tested the effect of Fbw7 inhibition on the overexpressed nuclear form of the SREBP-1c protein in transgenic livers (Figure 5). Production of nuclear SREBP-1c was stabilized by the transgene under the control of the PEPCK promoter. However, the amount of transgene SREBP-1c protein in liver nuclei was not elevated by Fbw7 knockdown, whereas c-Jun was accumulated (Figures 5A, 5B and 5C).

Fbw7 α Regulates Liver Triglyceride via KLF5/PPAR γ 2

Expression of SREBP-1c target genes such as FAS and SCD1 was not elevated consistently (Figure 5D). Nevertheless, after Fbw7i treatment, increased TG content was elevated further, and PPAR γ 2 expression was markedly up-regulated in SREBP-1c transgenic livers to the same extent as in wild-type livers (Figures 5E and 5F). These data suggested that Fbw7 knockdown did not affect the stability of the hepatic nuclear SREBP-1c protein *in vivo*. To directly evaluate the effects of Fbw7 knockdown on the uptake of fatty acids, mouse primary hepatocytes were prepared and infected with Fbw7i (Figure 6). Direct Fbw7 knockdown in primary hepatocytes increased the expression of PPAR γ 2 and CD36 (Figures 6A, 6B and 6C), leading to an increase in the estimated uptake of fatty acids (Figure 6D).

Conversely, the effects of Fbw7 α overexpression were tested (Figure 7). After the adenoviral overexpression of Fbw7 α , liver weight was slightly but significantly reduced, while the change in liver TG content was not significant (Figures 7A, 7B, and 7C). Adenoviral overexpression of Fbw7 α decreased c-Jun and its phosphorylated protein, but not its mRNA, confirming the enhancement of Fbw7 activity. Meanwhile, Fbw7 α overexpression caused parallel decreases in SREBP-1c mRNA as well as precursor and nuclear proteins (Figures 7D, 7E, and 7F). This finding does not support the

enhancement of SREBP-1c protein degradation by Fbw7 α *in vivo*. In contrast, Fbw7 α overexpression suppressed the expression of PPAR γ 2 and its target genes CD36, DGAT1/2, and Fsp27, but not GPAT as an SREBP-1 target (Figures 7G and 7H). mRNA levels of HMGCR and LDLR genes were not affected (data not shown). Overall, the effects of Fbw7 overexpression were consistently opposed to its inhibition, including the absence of an impact on SREBP-1c.

To confirm that PPAR γ 2 was responsible for the Fbw7 α -mediated regulation of hepatic TG metabolism, PPAR γ 2 knockdown was superimposed onto Fbw7 α knockdown in fatty liver (Figure 8). In double-knockdown animals, the induction of PPAR γ 2 expression by Fbw7 α knockdown (roughly 50% inhibition) was completely suppressed to the baseline level of the LacZi control (Figures 8A and 8B). As a result, the elevation of PPAR γ 2 target genes such as CD36, DGAT1, and Fsp27 by Fbw7 α knockdown was also inhibited completely by PPAR γ 2 knockdown, and the elevation of hepatic TG content by Fbw7 knockdown decreased considerably (Figures 8C and 8D). These data indicated that PPAR γ 2 mediated hepatic TG accumulation in the absence of Fbw7 α .

PPAR γ 2 is not regarded as a direct target protein of Fbw7-mediated degradation because its

Fbw7 α Regulates Liver Triglyceride via KLF5/PPAR γ 2

expression is repressed by Fbw7 α at the transcriptional level. Moreover, the protein lacks the Cdc4 phosphodegron (CPD) consensus (2) in its amino acid sequence as an Fbw7 target. CCAAT/enhancer binding protein (C/EBP) β and KLF5 are known as the transcription factors involved in PPAR γ 2 expression (41,42). KLF5 has been reported as a new target of Fbw7 (43,44), and KLF5, but not C/EBP β , which has the CPD consensus in its amino acid sequence (Figure 9A). Adenoviral knockdown or overexpression of Fbw7 α consistently up-regulated or suppressed KLF5, respectively (Figure 9B), but not C/EBP β , as estimated by immunoblot analysis of mouse hepatic proteins (data not shown). Fbw7 α -mediated degradation of KLF5 was investigated using the cycloheximide chase assay in Cos-7 cells. Fbw7 α enhanced the degradation of the KLF5 protein (Figure 9C). This degradation of the KLF5 protein by Fbw7 α was inhibited by the proteasome inhibitor ALLN in a way similar to the degradation of the SREBP-1 protein by Fbw7 α (Figures 9D and 9E). These data confirmed KLF5 as an Fbw7 target. Finally, the contribution of KLF5 to the Fbw7–PPAR γ 2 pathway was estimated using primary hepatocytes from KLF5 flox mice (Figure 10). Treatment of KLF5 flox hepatocytes with recombinant adenovirus expressing Cre recombinase (Ad-Cre) led to the essential deletion of KLF5 mRNA

(Figure 10A). KLF5-deleted hepatocytes decreased PPAR γ 2 expression, establishing KLF5 as an upstream transcription factor of PPAR γ 2. In control hepatocytes infected with Ad-GFP, PPAR γ 2 expression was increased by Fbw7i, as observed *in vivo* and returned to the basal level with KLF5 deletion (Figures 10B and 10C). These findings demonstrated that KLF5 mediates the Fbw7–PPAR γ 2 pathway.

To reveal the pathophysiological situation where Fbw7 α regulates PPAR γ 2, we tested the effect of PPAR α activation on pathological fatty liver. Obese mice such as db/db or ob/ob mice with leptin deficiency, exhibited severe hepatosteatosis with marked induction of PPAR γ 2 (42,45). Fibrates that have a PPAR α agonist action ameliorate fatty liver associated with a reduction in PPAR γ 2. The mechanism for this action has yet to be determined (46). In db/db mice, the level of nuclear Fbw7 protein was low, while KLF5 protein level was high compared with the control C57BL/6 mice. This suggests that Fbw7 contributes to PPAR γ 2 regulation (data not shown). Furthermore, ob/ob mice were treated with fenofibrate, and this system was examined (Figure 11). Interestingly, the PPAR α agonist caused strong induction of the nuclear Fbw7 protein, accompanied by a reduction in the KLF5 protein (Figure 11A). This explains the suppression of PPAR γ 2 and TG content by

Fbw7 α Regulates Liver Triglyceride via KLF5/PPAR γ 2

PPAR α activation (Figures 11B and 11C).

Discussion

Previous *in vitro* studies have suggested that Fbw7 is involved in the degradation of the nuclear SREBP protein (14). The present study was conducted to estimate the role of Fbw7 on the SREBP-1c system for lipogenesis *in vivo*. Unexpectedly, neither knockdown nor overexpression of Fbw7 α contributed to SREBP-1c protein levels in livers although our experimental settings on Fbw7 perturbation were strong enough for c-Jun, another target of Fbw7 α . No impact of Fbw7 α was observed on the nuclear SREBP-1c protein in the liver for a wide range of amounts of nuclear SREBP-1c protein in both wild type and SREBP-1c transgenic mice livers. This finding discounts the possibility of Fbw7 α contributing to *in vivo* regulation of liver SREBP-1c. The precise molecular mechanism for this discrepancy between *in vitro* and *in vivo* data is currently unknown. It has been proposed that the regulation of SREBP-1a stability by Fbw7 α in cultured cells may be related to the cell cycle and growth (14). In our experimental setting of Cos-7 cells, the impacts of Fbw7 α and the proteasome inhibitor ALLN on SREBP-1 proteins were also observed (Figure 9D). However, the cell growth-linked Fbw7 α /SREBP system may not

work in the liver, considering the long doubling time of hepatocytes.

The present findings demonstrated that Fbw7 α regulated TG metabolism in the liver. The gene expression pattern in Fbw7 α -knockdown livers indicated that Fbw7 regulated fatty acid uptake and TG synthesis, but not fatty acid synthesis or degradation, thereby highlighting the linkage of PPAR γ 2 and its target genes CD36, DGAT1, and Fsp27. In addition, the present study emphasized the physiological role of hepatic PPAR γ 2 in normal nutrition. In contrast to adipose tissue, PPAR γ 2 expression is low in the livers of mice on a normal diet. The suppression of PPAR γ 2 by Fbw7 α may contribute to this regulation and prevent unnecessary accumulation of hepatosteatosis during a normal energy state.

PPAR γ 2 is induced and involved in liver TG content in pathological fatty liver such as in ob/ob and diet-induced obesity (DIO) mice (47-50). However, hepatic Fbw7 α expression increased slightly under these conditions of overnutrition (data not shown). Fbw7 α overexpression had no effect on fatty liver in ob/ob mice. Fbw7 α did not appear to have a crucial effect on the regulation of liver TG content in overnutrition, where PPAR γ 2 induction occurs mainly through the trans-activation of C/EBP α and β (42). In contrast, PPAR α ameliorated fatty liver in these mice with a reduction in PPAR γ 2. Our data indicated that

Fbw7 α Regulates Liver Triglyceride via KLF5/PPAR γ 2

Fbw7 may mediate this inhibitory action of PPAR α on PPAR γ 2 and hepatosteatosis.

PPAR γ 2 is related to insulin resistance in ob/ob and DIO mice (48,49). Overexpression of PPAR γ 2 in livers ameliorated insulin resistance and decreased plasma levels of glucose and insulin in DIO mice, while ablation of PPAR γ 2 in ob/ob mice resulted in severe insulin resistance and an increase in plasma glucose levels. In the present study, significant decreases in plasma glucose and insulin were observed in Fbw7 knockdown mice, indicating that insulin sensitivity may be enhanced by up-regulation of hepatic PPAR γ 2 expression (Table 1).

Furthermore, our findings indicated that KLF5 was a direct target of Fbw7 *in vivo* and *in vitro*. Based on the data from KLF5-deleted hepatocytes, KLF5 could at least partially explain PPAR γ 2 up-regulation by suppression of hepatic Fbw7 α . As shown in Figure 10, the induction of PPAR γ 2 by Fbw7 knockdown was markedly impaired but

slightly remained in KLF5-deleted hepatocytes. This indicates that there could be some KLF5-independent mechanism. Careful interpretation of this molecular process is required as KLF5 may have various biological effects on cell growth (51,52) and secondary metabolic disturbances. Based on previous reports that c-Myc overexpression in transgenic mice contributed to glucose metabolism (53,54), it is possible that c-Myc, potentially induced by Fbw7i, could be involved in steatosis in Fbw7-knockdown livers.

Fbw7 is thought to be a cell growth regulator. The present study demonstrated an association of Fbw7 with hepatic fatty acid uptake and TG synthesis through PPAR γ 2 and not with lipogenesis through SREBP-1c. Further investigations are necessary to elucidate the precise roles of this versatile factor in light of the association between the nutritional regulation of lipid metabolism and regulation of cell growth.

Fbw7 α Regulates Liver Triglyceride via KLF5/PPAR γ 2

Acknowledgments

We are grateful to Prof. Oike for the helpful discussion. We also thank Dr. Tomotaka Yokoo and Motoki Mikami for the beneficial discussion and support. This work was supported by grants-in-aid from the Ministry of Education, Culture, Sports, Science and Technology of Japan.

Abbreviations

Fbw7, F-box and WD repeat domain-containing 7; SCF, Skp1-Cul1-F-box protein ubiquitin ligase; FAS, fatty acid synthase; Elovl6, long chain fatty acid elongase; SCD, stearyl-CoA desaturase; SREBP, sterol regulatory element binding protein; LDLR, low density lipoprotein receptor; DGAT, diacylglycerol acyltransferase; GPAT, mitochondrial glycerol-3-phosphate acyltransferase; HMGCR, HMG-CoA reductase; PEPCK, phosphoenolpyruvate carboxykinase; KLF5, Krüppel-like factor 5; C/EBP, CCAAT/enhancer binding protein; CPD, Cdc4 phosphodegron; DIO, diet-induced obesity; *ob/ob*, B6.V-*Lep*^{ob}/J; TG, triglyceride; TC, total cholesterol; NEFA, non-esterified fatty acid; AST, aspartate aminotransferase; ALT, alanine aminotransferase.

Fbw7 α Regulates Liver Triglyceride via KLF5/PPAR γ 2

Figure Legends

FIGURE 1. ***In vivo* effects of Fbw7 knockdown in livers of C57BL/6J mice.** Eight- to nine-week-old male C57BL/6J mice were infected through the tail vein with adenovirus encoding RNAi targeting Fbw7 (Fbw7i) or LacZ (LacZi) sequences (adenoviral dose of 2.5×10^{11} viral particles per mouse). After 4 days of standard chow feeding, the mice were sacrificed in the non-fasted state.

A: Fbw7 mRNA levels in the livers of mice infected with LacZi or Fbw7i, as determined by real-time PCR (graph) or northern blot analysis (insert). The quantities of mRNA were calculated as the ratio of the cyclophilin level in each cDNA sample. Data are shown as the expression ratio relative to the LacZi control group. *B:* Abdominal (top) and hepatic (bottom) views of mice infected with LacZi or Fbw7i. Liver weights (*C*), epididymal white adipose tissue (WAT) weights (*D*), liver histology (hematoxylin and eosin staining, $\times 200$) (*E*), liver triglyceride (TG) contents (*F*), and liver total cholesterol (TC) contents (*G*) of mice infected with LacZi or Fbw7i. $n = 9$ per group in (*A*), (*C*), (*D*), and (*F*), and $n = 4$ per group in (*G*). Statistical analysis was performed using unpaired Student's *t*-test; ** $p < 0.01$ (versus LacZi control group).

FIGURE 2. **Effects of Fbw7 knockdown on the protein and mRNA expression in the livers of C57BL/6J mice.** All mice were infected with Fbw7i or LacZi adenovirus. After 4 days of standard chow feeding the mice were sacrificed in the non-fasted state.

A: Immunoblot analysis of the cleaved nuclear forms of SREBP-1 (nSREBP-1), c-Jun, phosphorylated c-Jun (P-c-Jun), and Lamin A/C as an internal control in nuclear extracts and precursor forms of SREBP-1 (pSREBP-1) and α -tubulin as an internal control in whole cell lysates from mouse livers. Each protein sample was obtained from 3–5 mice infected with LacZi or Fbw7i. Protein levels of the Fbw7i group displayed below each blot are shown as the mean \pm SEM of the relative quantity ratios to the LacZi control group in 3–5 independent experiments. The protein quantities were determined as described in the experimental procedures and normalized by the respective internal control. *B:* mRNA levels of cJun. *C:* mRNA levels of SREBP-1c, acetyl-CoA carboxylase (ACC), fatty acid synthase (FAS), long chain fatty acid elongase 6 (Elovl6), stearoyl-CoA desaturase (SCD) 1, and carbohydrate responsive element binding protein (ChREBP). *D:* mRNA levels of PPAR α and its regulated genes acyl-CoA oxidase (ACO) and medium chain acyl-CoA dehydrogenase (MCAD). mRNA levels of PPAR γ 1, PPAR γ 2, aP2 (*E*), and CD36,

Fbw7 α Regulates Liver Triglyceride via KLF5/PPAR γ 2

mitochondrial glycerol-3-phosphate acyltransferase (GPAT), diacylglycerol acyltransferase 1/2 (DGAT1/2), and fat-specific protein 27 (Fsp27) (*F*). All RNA samples were extracted from the livers of mice infected with LacZi or Fbw7i. The quantities of mRNA were determined by real-time PCR and normalized by the cyclophilin level in each cDNA sample. mRNA levels are shown as the expression ratio relative to the LacZi control group. $n = 3-5$ per group in (*A*), $n = 4-9$ per group in (*C*) and (*F*), $n = 4$ per group in (*B*) and (*D*), and $n = 7-9$ per group in (*E*). Statistical analysis was performed using one sample *t*-test in (*A*) and unpaired Student's *t*-test in all other panels; ** $p < 0.01$ and * $p < 0.05$ (versus LacZi control group).

FIGURE 3. Effects of Fbw7 knockdown on gene expression in the livers of C57BL/6J mice. All mice were infected with Fbw7i or LacZi adenovirus. After 4 days of standard chow feeding the mice were sacrificed in the non-fasted state.

mRNA levels of LDL receptor (LDLR) and HMG-CoA reductase (HMGCR) (*A*), apolipoprotein B (ApoB) and microsomal triglyceride transfer protein (MTTP) (*B*), glucose-6-phosphatase (G6Pase), phosphoenolpyruvate carboxykinase (PEPCK), glucose transporter 2 (GLUT2), and glucokinase (GK) (*C*), and IL-1 β and IL-6 (*D*) in the livers of mice infected with LacZi or Fbw7i determined by real-time PCR. The quantities of mRNA were calculated as the ratio of the cyclophilin level in each cDNA sample. mRNA levels are shown as the expression ratio relative to the LacZi control group. $n = 4$ per group in (*A*) and (*C*), and $n = 8$ or 9 per group in (*B*) and (*D*). Statistical analysis was performed using unpaired Student's *t*-test; ** $p < 0.01$ and * $p < 0.05$ (versus LacZi control group).

FIGURE 4. Effects of Fbw7 knockdown on gene expression and TG contents in the livers of SREBP1-KO. Six- to eight-week-old male SREBP1-KO and littermates were infected through the tail vein with Fbw7i or LacZi adenovirus (adenoviral dose of 2.5×10^{11} viral particles per mouse).

After 4 days of standard chow feeding, the mice were sacrificed in the non-fasted state.

A: Fbw7 α mRNA levels in the livers of SREBP1-KO and littermates infected with LacZi or Fbw7i determined by real-time PCR. *B*: Liver TG contents of SREBP1-KO and littermates infected with LacZi or Fbw7i. *C*: Immunoblot analysis of cleaved nSREBP-1, c-Jun, P-c-Jun, and Lamin A/C as an internal control in nuclear extracts from the livers of 4 or 5 mice in each group indicated.

Quantification results were obtained as described in the experimental procedures and normalized by the internal control. Relative changes compared to controls (littermates infected with LacZi) are displayed below each blot. The mRNA levels of FAS and SCD1 (*D*), HMG-CoA reductase (HMGCR) (*E*), and PPAR γ 2 and CD36 (*F*) in the livers of SREBP1-KO and littermates infected with

Fbw7 α Regulates Liver Triglyceride via KLF5/PPAR γ 2

LacZi or Fbw7i. The quantities of mRNA were determined by real-time PCR and normalized by the cyclophilin level in each cDNA sample. mRNA levels were shown as the expression ratio relative to the LacZi control group. $n = 4$ or 5 per group in all panels. Statistical analysis was performed using unpaired Student's *t*-test; ** $p < 0.01$ (versus respective LacZi control group).

FIGURE 5. Effects of Fbw7 knockdown on gene expression and TG contents in the livers of SREBP-1c transgenic mice (SREBP1c-Tg). Thirteen-week-old male SREBP1c-Tg and littermates were infected through the tail vein with Fbw7i or LacZi adenovirus (adenoviral dose of 2.5×10^{11} viral particles per mouse). After 4 days of standard chow feeding, the mice were sacrificed in the non-fasted state.

A: Fbw7a mRNA levels in the livers of SREBP1c-Tg and littermates infected with LacZi or Fbw7i. *B:* Immunoblot analysis of the cleaved nuclear forms of SREBP-1 (nSREBP1), c-Jun, and Lamin A/C as an internal control in nuclear extracts from the livers of 5 mice in each group indicated. Quantification results were obtained as described in the experimental procedures and normalized by the internal control. Relative changes compared to controls (littermates or SREBP1c-Tg infected with LacZi) are displayed below each blot. mRNA expression of exogenous human SREBP-1c (hSREBP-1c) (*C*) and FAS and SCD1 (*D*) in the livers of SREBP1c-Tg and littermates infected with LacZi or Fbw7i. ND, not detected. *E:* Liver TG contents of SREBP1c-Tg and littermates infected with LacZi or Fbw7i. *F:* mRNA levels of PPAR γ 2 in the livers of SREBP1c-Tg and littermates infected with LacZi or Fbw7i. mRNA quantities were determined by real-time PCR and calculated as the ratio of the cyclophilin level in each cDNA sample. Data are shown as the expression ratio relative to the LacZi control group. $n = 5$ per group in all panels. Statistical analysis was performed using unpaired Student's *t*-test; ** $p < 0.01$ and * $p < 0.05$ (versus respective LacZi control group).

FIGURE 6. Influence of Fbw7 knockdown on fatty acid uptake in mouse primary hepatocytes.

Primary hepatocytes were isolated from C57BL/6J mice and infected with Fbw7i or LacZi adenovirus (1000 virus particles/cell) and cultured for 48 h. [1- 14 C]palmitate uptake of the treated primary hepatocytes was measured, as indicated in the experimental procedures.

mRNA levels of Fbw7 α (*A*), PPAR γ 2 (*B*), and CD36 (*C*) in mouse primary hepatocytes infected with LacZi or Fbw7i. The quantities of mRNA were determined by real-time PCR and normalized by the cyclophilin level in each cDNA sample. mRNA levels are shown as the expression ratio relative to the LacZi control group. *D:* [1- 14 C]palmitate incorporation into cellular lipid in mouse primary hepatocytes infected with LacZi or Fbw7i. All experiments were performed using five sets of primary

Fbw7 α Regulates Liver Triglyceride via KLF5/PPAR γ 2

hepatocytes for each group. Statistical analysis was performed using unpaired Student's *t*-test; ** $p < 0.01$ (versus LacZ α control group).

FIGURE 7. *In vivo* effects of Fbw7 α overexpression in the livers of C57BL/6J mice.

Fourteen-week-old male C57BL/6J mice were infected through the tail vein with adenovirus encoding GFP (Ad-GFP) as the control or mouse Fbw7 α (Ad-Fbw7 α) (adenoviral dose of 1.5×10^{11} viral particles per mouse). After 6 days of standard chow feeding, the mice were sacrificed in the non-fasted state.

A: mouse Fbw7 α mRNA levels in livers of mice infected with Ad-GFP or Ad-Fbw7 α determined by real-time PCR (graph) and Fbw7 α protein levels, examined by immunoblot analysis (insert). Liver weights (*B*) and liver TG contents (*C*) of the mice infected with Ad-GFP or Ad-Fbw7 α . *D*: Immunoblot analysis of cleaved nuclear forms of SREBP-1 (nSREBP-1), c-Jun, P-c-Jun, and Lamin A/C as an internal control in nuclear extracts, and precursor forms of SREBP-1 (pSREBP-1) and α -tubulin as an internal control in whole cell lysates from mouse livers. Each protein sample was obtained from 3–5 mice infected with Ad-GFP or Ad-Fbw7 α . Protein levels of the Ad-Fbw7 α group displayed below each blot are shown as the mean \pm SEM of the relative quantity ratios to the Ad-GFP control group in 3 independent experiments. The protein quantities were determined as described in the experimental procedures and normalized by the respective internal control. The mRNA levels of SREBP-1c, ACC, FAS, Elovl6, and SCD1 (*E*), c-Jun (*F*), PPAR γ 1 and PPAR γ 2 (*G*), and CD36, GPAT, DGAT1/2, and Fsp27 (*H*) in the livers of mice infected with Ad-GFP or Ad-Fbw7 α . The quantities of mRNA were determined by real-time PCR and normalized by the cyclophilin level in each cDNA sample. The mRNA levels are shown as the expression ratio relative to the Ad-GFP control group. $n = 3$ per group in (*D*) and $n = 5$ per group in all other panels. Statistical analysis was performed using one sample *t*-test in (*A*) and unpaired Student's *t*-test in all other panels; ** $p < 0.01$ and * $p < 0.05$ (versus Ad-GFP control group).

FIGURE 8. Effects of Fbw7 and PPAR γ 2 double knockdown on gene expression and TG contents in the livers of C57BL/6J mice.

Nine-week-old male C57BL/6J mice were infected through the tail vein with adenovirus encoding RNAi targeting PPAR γ 2 (PPAR γ 2i), Fbw7 (Fbw7i), and/or LacZ (LacZi) sequence (adenoviral dose of 2.5×10^{11} viral particles per mouse). After 4 days of standard chow feeding, the mice were sacrificed in the non-fasted state.

The mRNA levels of Fbw7 α (*A*), PPAR γ 1 and PPAR γ 2 (*B*), and CD36, DGAT1, and Fsp27 (*C*) in livers of mice treated with LacZi alone (LacZi), Fbw7i and LacZi (Fbw7i), or Fbw7i and PPAR γ 2i

Fbw7 α Regulates Liver Triglyceride via KLF5/PPAR γ 2

(Fbw7i + PPAR γ 2i). *D*: The liver TG contents of these three groups are as described above. The quantities of mRNA were determined by real-time PCR and normalized by the cyclophilin level in each cDNA sample. mRNA levels are shown as the expression ratio relative to the LacZi control group. $n = 4$ or 5 per group in all panels. Statistical analysis was performed using two-way ANOVA followed by Tukey's procedure; ** $p < 0.01$ and * $p < 0.05$ (versus LacZi) and ## $p < 0.01$ (versus Fbw7i).

FIGURE 9. Fbw7 α -mediated degradation of Krüppel-like factor 5 (KLF5).

A, Amino acid sequence alignment of the Cdc4 phosphodegron (CPD) in cyclin E, c-Myc, c-Jun, and KLF5. *B*, Immunoblot analysis of KLF5 and Lamin A/C as an internal control in nuclear extracts from the livers of 4 or 5 mice infected with LacZi, Fbw7i, Ad-GFP (GFP), or Ad-Fbw7 α (Fbw7 α). Quantification results were obtained as described in the experimental procedures and normalized by the internal control. The changes relative to the controls (LacZi or GFP) are displayed below each blot. *C*: Cos-7 cells were transfected with KLF5 in the presence or absence of Fbw7 α . Thirty-six hours after transfection, the cells were either lysed directly or incubated in the presence of cycloheximide (100 μ g/mL) for the time period indicated to determine KLF5 turnover. The levels of KLF5 were determined by immunoblot analysis. *D*: Cos-7 cells were transfected with the SREBP-1c expression plasmid in the presence or absence of Fbw7 α . Thirty-six hours after transfection, the cells were treated with vehicle alone (DMSO) or ALLN (50 μ g/mL) for 4 h prior to cell lysis. The protein levels of SREBP-1c, Fbw7 α , and α -tubulin were determined by immunoblot analysis. *E*: Cos-7 cells were transfected with the KLF5 expression plasmid in the presence or absence of Fbw7 α . Thirty-six hours after transfection, the cells were treated with vehicle alone (DMSO) or ALLN (50 μ g/mL) for 4 h prior to cell lysis. The protein levels of KLF5, Fbw7 α , and α -tubulin were determined by immunoblot analysis.

FIGURE 10. Contribution of KLF5 to Fbw7-mediated inhibition of PPAR γ 2.

Primary hepatocytes prepared from KLF5 flox mice were seeded in 6-cm plates and infected with Fbw7i or LacZi (1000 virus particles/cell) and Ad-GFP as the control or Ad-Cre recombinase encoding adenovirus (Ad-Cre) (300 virus particles/cell). Infected hepatocytes were cultured for 48 h, and the mRNA levels in treated hepatocytes determined by real-time PCR.

The mRNA levels of KLF5 (*A*), Fbw7 α (*B*), and PPAR γ 2 (*C*) in mouse primary hepatocytes infected with LacZi or Fbw7i and Ad-GFP or Ad-Cre. The quantities of mRNA were determined by real-time PCR and normalized by the cyclophilin level in each cDNA sample. mRNA levels are shown as the

Fbw7 α Regulates Liver Triglyceride via KLF5/PPAR γ 2

expression ratio relative to both the LacZi- and Ad-GFP-infected control groups. All experiments were performed using four sets of primary hepatocytes for each group. Statistical analyses were performed using two-way ANOVA followed by Tukey's procedure; * $p < 0.05$ (versus LacZi of each group) and # $p < 0.05$ (versus LacZi or Fbw7i of Ad-GFP group).

FIGURE 11. Effects of fenofibrate administration on gene expression and TG contents in the livers of ob/ob mice. Eight-week-old male ob/ob mice were fed a control diet (ob/ob Fen $^{-}$) or 0.1% fenofibrate diet (ob/ob Fen $^{+}$) for 7 days. All mice were sacrificed in the non-fasted state. *A*: Immunoblot analysis of Fbw7 α , KLF5, and Lamin A/C as an internal control in nuclear extracts from the livers of 5 mice in each group indicated. Quantification results were obtained as described in the experimental procedures and normalized by the internal control. The changes relative to the controls (ob/ob Fen $^{-}$) are displayed below each blot. *B*: PPAR γ 2 mRNA levels in livers of ob/ob mice treated with control or 0.1% fenofibrate diet. The quantities of mRNA were determined by real-time PCR and normalized by the cyclophilin level in each cDNA sample. mRNA levels are shown as the expression ratio relative to the ob/ob Fen $^{-}$ control group. *C*: Liver TG contents of ob/ob mice treated with control or 0.1% fenofibrate diet. $n = 8$ or 9 per group in (*B*) and $n = 5$ per group in (*C*). Statistical analysis was performed using unpaired Student's *t*-test; ** $p < 0.01$ and * $p < 0.05$ (versus ob/ob Fen $^{-}$).

Fbw7 α Regulates Liver Triglyceride via KLF5/PPAR γ 2**TABLE 1****Plasma metabolic parameters in the Fbw7 knockdown mice.**

Data are the mean \pm SEM of 4 male C57BL/6J mice in the non-fasted state at day 4 after adenovirus infection.

Parameter	LacZi	Fbw7i
Body weight (g)	25.3 \pm 0.47	24.6 \pm 0.15
Glucose (mg/dL)	252 \pm 8.3	191 \pm 14*
Insulin (pg/mL)	0.30 \pm 0.083	0.057 \pm 0.036*
TG (mg/dL)	151 \pm 6.4	92 \pm 1.2**
TC (mg/dL)	67.4 \pm 6.9	88.2 \pm 6.7
NEFA (mEq/L)	1.21 \pm 0.04	1.14 \pm 0.08
ALT (Karmen unit)	30 \pm 1.6	42 \pm 1.0**
AST (Karmen unit)	63 \pm 4.8	114 \pm 5.4**

* p < 0.05 and ** p < 0.01 (versus each respective LacZi control).
