Abstract

Expression of antioxidant enzymes is regulated by transcription factor NF-E2-related factor (Nrf2) and induced by oxidative stress. Reactive oxygen species contribute to the formation of several types of cochlear injuries, including age-related hearing loss and gentamicin ototoxicity. In this study, we examined the roles of Nrf2 in age-related hearing loss and gentamicin ototoxicity by measuring auditory brainstem response thresholds in Nrf2-knockout mice. Although Nrf2-knockout mice maintained normal auditory thresholds at 3 months of age, their hearing ability was significantly more impaired than that of age-matched wild-type mice at 6 and 11 months of age. Additionally, the numbers of hair cells and spiral ganglion cells were remarkably reduced in Nrf2-knockout mice at 11 months of age. To examine the importance of Nrf2 in protecting against gentamicin-induced ototoxicity, 3-day-old mouse organ of Corti explants were cultured with gentamicin. Hair cell loss caused by gentamicin treatment was enhanced in the Nrf2-deficient tissues. Furthermore, the expressions of some Nrf2-target genes were activated by gentamicin treatment in wild-type mice but not in Nrf2-knockout mice. The present findings indicate that Nrf2 protects the inner ear against age-related hearing injuries and gentamicin ototoxicity by up-regulating antioxidant enzymes and detoxifying proteins.
Keywords

NF-E2-related factor (Nrf2); reactive oxygen species (ROS); cochlea; age-related hearing loss (AHL); gentamicin ototoxicity
Introduction

The antioxidant responsive element (ARE) is a cis-acting regulatory element, through which Nrf2 regulates transcription of genes encoding phase II detoxification enzymes, antioxidants, and other factors essential for cell survival. Under normal conditions, Nrf2 is anchored in the cytoplasm through interaction with Kelch-like ECH-associated protein 1 (Keap1) and subsequently proteolyzed by proteasomes. In contrast, under oxidative stress conditions, Keap1-censored electrophiles inhibit the proteolysis of Nrf2. Having thus escaped Keap1-mediated proteolysis, Nrf2 accumulates in the nucleus and activates ARE-mediated gene transcription [1,2]. To date, many genes driven by Nrf2, including heme oxygenase 1 (HO1), NAD(P)H:quinone oxidoreductase 1 (NQO1), NHR:quinone oxidoreductase 2 (NQO2), glutathione peroxidase (GPx), superoxide dismutase 1 (SOD1), and peroxiredoxin 1 (Prx1), have been reported to be involved in the antioxidant defense system [3-5].

Accumulated evidence suggests that reactive oxygen species (ROS) are involved in the pathogenesis of a wide range of cochlear injuries, including cochlear ischemia-reperfusion injury [6-9], acoustic injury [10-12], aminoglycoside ototoxicity [13], and age-related hearing loss (AHL) [14]. Because ROS are one of the Nrf2-inducing stressors, Nrf2-ARE responses are predicted to give rise to cochlear injuries. However,
little is known about the protective role of Nrf2 in the cochlear pathophysiology.

In contrast, several contributions of Nrf2-driven antioxidant enzymes to the cochlea have been revealed. For example, SOD1 is one of the best-characterized enzymes in the cochlear pathology. Age-related hearing loss was accelerated in SOD1-knockout (KO) mice [15,16], and SOD1-KO mice are more susceptible to noise-induced hearing loss [17]. Acoustic injury was also reported to be prevented by tempol, a SOD-mimetic agent [11]. Furthermore, HO1 and GPx effectively work to prevent inner ear injury after exposure to oxidative stresses [18-21]. Since Prxl scavenges hydrogen peroxide, lipid hydroperoxide, and peroxynitrite, Prxl is thought to contribute to the prevention of oxidative injury in the cochlea.

Here, we examined the contribution of Nrf2 to cochlear protection by using Nrf2-KO mice. The results from the auditory brainstem response (ABR) and morphological analyses indicated significant impairment of auditory function in aged mice in the absence of Nrf2. Furthermore, the cochlear cells of Nrf2-KO mice were severely injured after gentamicin treatment, to the extent that they lacked the expression of several Nrf2-driven antioxidant enzymes. These analyses of Nrf2-KO mice provide new insight into preventive medical procedures for age-related and drug-induced hearing loss.
Materials and Methods

Animals

Nrf2-KO mice were produced and maintained on a BDF1 background as previously described [2]. Wild-type BDF1 mice were used as the control. The animals were maintained under a normal day/night cycle and given free access to food and water. The care and use of animals were approved by the Animal Research Committee and Safety Committee for Gene Recombination Research of the University of Tsukuba.

ABR testing

Mice were anesthetized with an intraperitoneal injection of pentobarbital sodium (Nembutal; Abbott Laboratories, Chicago, IL). Anesthesia was supplemented during the course of measurement of ABR as necessary.

Positive, negative, and ground electrodes were subcutaneously inserted at the vertex, mastoid, and back, respectively [11,12,22]. Bursts of 4, 8, or 16 kHz pure tones were used to evoke ABR. Evoked responses were amplified, filtered with a bandpass of 200 Hz to 3 kHz, and averaged with 500 sweeps using a signal processor (Synax2100; NEC, Tokyo, Japan). The visual detection threshold was determined with increment or decrement of sound pressure at 5 dB steps.
Staining of hair cells

Eleven-month-old mice were transcardially perfused with 4% paraformaldehyde under deep anesthesia with pentobarbital sodium. After decapitation, the cochleae were kept in the same fixative at 4°C overnight, decalcified with ethylenediaminetetraacetic acid (EDTA), and then dissected for surface preparation. Whole mounts of the organ of Corti were permeabilized with 5% TritonX-100 (Sigma, St Louis, MO) in phosphate-buffered saline (PBS) with 10% fetal bovine serum (FBS) for 10 minutes. The specimens were stained with a rhodamine-phalloidin probe (1:100; Invitrogen, Carlsbad, CA) at room temperature for 1 hour [23]. Phalloidin specifically binds to cellular F-actin and is used to visualize the stereociliary arrays and cuticular plate of hair cells.

Assessment of hair cell damage

A hair cell was characterized as “missing” if neither the stereocilia nor the cuticular plate were observed in the cell by phalloidin staining. Quantitative results were obtained by evaluating 30 outer hair cells associated with 10 inner hair cells in a given microscopic field. The average of 5 separate counts was used to represent each
specimen [23,24].

**Assessment of spiral ganglion cells**

The Nrf2-KO and wild-type mice were killed at 11 months of age. The cochleae were fixed with 4% paraformaldehyde, decalcified with EDTA, and then embedded in paraffin. The cochleae were cut into 5-μm-thick midmodiolar sections. After the sections were stained with hematoxylin and eosin, the number of spiral ganglion cells was counted.

**Culture techniques**

The basal turn of the organ of Corti was dissected from the mice on postnatal day 3 (P3). The methods for culture of the organ of Corti were previously reported [23]. The explants were maintained in Dulbecco’s modified Eagles medium (DMEM) with 10% FBS, 25 mM 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid, and 30 U/mL penicillin and cultured in an incubator at 37°C with 5% CO2 and 95% humidity with or without gentamicin treatment at a concentration of 50 μM. For the morphological analysis, after 72 hours of culture, the explants were fixed with 4% paraformaldehyde in PBS for 20 minutes and then permeabilized with 5% TritonX-100 in PBS with 10% FBS for 10
minutes [23,24]. The specimens were stained with a rhodamine-phalloidin probe, as described above.

**RT-PCR**

Dissected cochleae of P3-5 pups were cultured in DMEM media as described above for up to 24 hours. Total RNAs were isolated from the culture specimens using an Isogen RNA preparation kit (Nippon Gene, Tokyo, Japan). The cDNA samples were synthesized with SuperScript II reverse transcriptase (Invitrogen, Carlsbad, CA). qPCR Mastermix (Nippon Gene, Tokyo, Japan) was used for the analyses of the HO1 and NQO1 genes and a Power SYBR Green RNA-to-CT 1 step kit (Applied Biosystems, Carlsbad, CA) for the SOD1 and Prxl genes according to the manufacturer’s instructions. Real-time RT-PCR was performed using an ABI-PRISM 7700 Sequence Detector System (Applied Biosystems, Carlsbad, CA). The primers were as follows, and otherwise were described previously [25]:

\[(SOD1 \text{ forward: } 5'-\text{GACAAACCTGAGCCCTAAG-3'}; \quad SOD1 \text{ reverse: } 5'-\text{CGACCTTGCTCCTTATTG-3'}; \quad Prxl \text{ forward: } 5'-\text{CGTTCTCAGGCCTTTCTGT3'}; \quad Prxl \text{ reverse : } 5'-\text{GCATTCCTGAAGACATCTTGCT-3'}).\]
**Statistical analyses**

All data were evaluated by the *t* test or two-way ANOVA. Any test resulting in a *p* value of less than 0.05 was considered significant. Error bars represent the standard error of means.
Results

Hearing ability deteriorates rapidly with increasing age in Nrf2-KO mice.

To elucidate the contribution of Nrf2 to the auditory organ, we examined hearing thresholds in Nrf2-KO mice by measuring the ABR thresholds. The ABR thresholds in the Nrf2-KO and age-matched wild-type mice at 3 months of age were not significantly different (Fig. 1). Next, to elucidate age-induced changes in hearing ability, we measured the ABR thresholds of the mice at 6 and 11 months of age. Expectedly, the ABR thresholds of the wild-type mice were elevated in an age-dependent manner (Fig. 1). Notably, the ABR thresholds of the 6- and 11-month-old Nrf2-KO mice rose to much higher levels than those of the age-matched wild-type mice (Fig. 1). These results indicated that Nrf2 was involved in maintaining hearing function in older mice.

Hair cells and spiral ganglion cells are missing in aged Nrf2-KO mice.

To elucidate the reason for the hearing disturbance in older Nrf2-KO mice, the cochlear morphology was microscopically examined and phalloidin staining used to observe the hair cells. As shown in Figure 2A, degeneration of the outer hair cells was apparent in the first cochlear region, while hair cell loss in the second turn and the region of inner hair cells was not obvious in the 11-month-old wild-type mice (Fig. 2A),
consistent with previous reports. In contrast, the cochlear architecture of the Nrf2-KO mice was destroyed in the outer hair cell layer, and the hair cell loss extended into the inner hair cell layer of the second turn (Figure 2A). We next attempted quantitative analyses of the hair cells. In good agreement with the morphological analyses, the number of residual outer hair cells was significantly more decreased in the Nrf2-KO mice than in the age-matched wild-type mice ($p<0.001$, two-way ANOVA; Fig. 2B, upper panel). In addition, significant inner hair cell loss in the first turn of the Nrf2-KO mouse cochlea was also observed ($p<0.05$, two-way ANOVA) (Fig. 2B, lower panel).

Next, the ganglion cell population in the midmodiolar sections in the 11-month-old Nrf2-KO and wild-type mice was counted. Microphotographs of the lower first and lower second turns of these mice showed spiral ganglion cells in the Rosenthal canal (Fig. 3A). Loss of spiral ganglion cells in the lower turn of the cochlea was clearly observed in both the wild-type and the Nrf2-KO mice (Fig. 3A). On the other hand, spiral ganglion cell density in the upper turn was also decreased in the Nrf2-KO mice, whereas it was comparatively maintained in the wild-type mice (Fig. 3A). Quantitative analysis of the spiral ganglion cells in each turn revealed that the number of residual spiral ganglion cells was significantly more decreased in the Nrf2-KO mice than in the wild-type mice ($p<0.05$, two-way ANOVA). Taken together, hair cell loss and spiral ganglion cell loss
rapidly progressed with age in Nrf2-KO mice, causing significant hearing impairments in older mice.

**Nrf2 knockout accelerated gentamicin ototoxicity.**

Nrf2 regulates expression of genes that protect cells from oxidative damage. To investigate the roles of Nrf2 in protection against oxidative stress in the cochlea, we attempted explant organ culture in the presence of gentamicin. Gentamicin is a well-known ototoxic drug, and its ototoxicity is involved in the ROS- and nitric oxide-related mechanisms.

Hair cell explants were dissected from P3 pups of Nrf2-KO and wild-type mice. Subsequently, the explants were incubated in 50 μM gentamicin for 72 hours. As shown in Figure 4A, the outer hair cells were severely damaged in the Nrf2-KO mice. Quantitative analysis revealed that the number of residual outer hair cells was much more decreased in the Nrf2-KO mice than in the wild-type mice (p<0.01, t test) (Fig. 4B).

We next examined the expression of Nrf2-dependent enzymes in the cultured cochleae exposed to gentamicin. As shown in Figure 4C, the mRNA levels of HO1, NQO1, and SOD1 in the wild-type mice were increased at 6 hours and had recovered to the basal level at 24 hours after gentamicin exposure. On the other hand, such induction
was not observed in the *Nrf2-KO* mice during the observation period. Especially, the expression of *NQO1* and *SOD1* genes after 6-hour exposure was significantly more elevated in the wild-type mice than in the *Nrf2-KO* mice (*p*<0.05, *t* test). In contrast, induction by gentamicin of *Prxl* gene expression was not detected in either the wild-type mice or the *Nrf2-KO* mice during this experiment. These findings suggest that Nrf2 protects the cochlear from gentamicin ototoxicity through induction of antioxidant enzymes.
Discussion

Reactive oxygen species are involved in a wide range of cochlear injuries [6-14]. In addition, AHL is ascribed to the production of ROS, at least in part [26]. Nrf2 is believed to protect against oxidative tissue damage through ARE-mediated transcriptional activation of several phase II detoxifying enzymes and antioxidant enzymes. However, little is known about the function of Nrf2 in the cochlea. So et al. demonstrated the roles of Nrf2 in the protection of cisplatin-induced hair cell loss via \textit{HO1} gene activation by means of an \textit{ex vivo} organ culture assay [20]. Furthermore, recent work using mice suffering from progressive hearing loss demonstrated that sulforaphane, an Nrf2 inducer, was effective in alleviating the mouse phenotype [27]. Hence, the molecular dissection of the Nrf2 function in the cochlea has become very important for the development of preventive strategies for patients at high risk of ear damage. In this study, we clarified the importance of Nrf2 in the cochlea in protecting against AHL and ototoxic agents by using genetically manipulated \textit{Nrf2-KO} mice.

The spiral shape of the cochlea was not disturbed in \textit{Nrf2-KO} mice. In addition, the hearing ability of these mice was within normal levels until 3 months of age. In contrast, the hearing ability of \textit{Nrf2-KO} mice rapidly worsened with age in comparison with that of wild-type mice and was accompanied by significant loss of hair cells and spiral ganglion
cells. Therefore, we surmise that Nrf2 is preventive against progression of AHL, while loss of Nrf2 is dispensable during auditory organ development.

Aminoglycoside antibiotics, such as gentamicin, are ototoxic drugs damaging to cochlear hair cells. As in cisplatin-induced ototoxicity, ROS are one of the leading factors involved in aminoglycoside-induced cochlear injury. We here demonstrated that Nrf2 protects against progression of gentamicin-induced hair cell damage by regulating antioxidant enzymes. The expression of \( \text{NQO1} \) and \( \text{SOD1} \), which are representative ARE-dependent Nrf2-mediated detoxifying/antioxidant enzymes, was significantly upregulated after 6-hour gentamicin exposure in wild-type mice, but such upregulation was not observed in \( \text{Nrf2-KO} \) mice. We surmise that in a similar manner to these 2 genes, HO1 is cooperatively involved in otoprotection, since it is one of the important Nrf2-mediated enzymes against oxidative stress-induced inner ear injury. We could not detect any significant difference in \( \text{HO1} \) gene induction by gentamicin exposure between the wild-type and \( \text{Nrf2-KO} \) mice, probably because the expression of HO1 is regulated by a combination of Nrf2 and Bach1, which is another b-Zip protein Bach1 [28]. Further analysis using \( \text{Nrf2-} \) and \( \text{Bach1-double KO} \) mice is required to clarify the regulation of HO1 in the cochlea by gentamicin exposure. It is noteworthy that the expression of such Nrf2-target genes was increased in a transient manner when the
induction response was complete by 24 hours. This result is somewhat unexpected because the induction of Nrf2 target genes by conventional Nrf2-inducers usually continues beyond 24 hours. It was previously reported that a transient response by diethyl maleate, a strong Nrf2 inducer, was observed in \textit{HO1} but not in \textit{NQO1} gene expression because of a gene-specific epigenetic modification [29]. We speculate that a variety of modification mechanisms divers the gene regulation profiles depending on the tissue identity.

In conclusion, the present study demonstrated that disruption of Nrf2 causes AHL and renders the cochlea vulnerable to gentamicin ototoxicity. Although Nrf2 does not contribute to the formation of the inner ear in the developmental period, it cleans up the ROS induced by several postbirth environmental factors, thereby minimizing AHL-related cochlear injuries. We propose that compounds that activate Nrf2 prevent progression of cochlear injury related to AHL and ototoxic agents.
