Abstract: 1,1-Difluoroallenes are synthesized in good yield via zinc-promoted 1,2-elimination of 3,3-difluoro-2-iodoallylic acetates, which are prepared by the reaction of aldehydes or ketones with 1-iodo-2,2-difluorovinylithium, generated from commercially available 1,1,1-trifluoro-2-iodoethane.

Key words: fluorinated allenes, metalation, carbanions, elimination, difluorovinylation.

1,1-Difluoroallenes have attracted much attention because of their unusual reactivities, which leads to them being used as synthetic building blocks for fluorinated molecules. The Diels–Alder and [3+2] cycloaddition reactions of 1,1-difluoroallenes with 1,3-dienes and 1,3-dipoles readily take place on the internal, non-fluorinated alkene moiety to give the corresponding exo-difluoromethylene compounds.1 For example, 1,1-difluoroallene (CF₂=C=CH₂), with a low LUMO energy level, gives an excellent yield (>99%) of the cyclized product with cyclopentadiene under very mild conditions (–20 ºC, 1 min), while the non-fluorinated counterpart (CH₂=C=CH₂) requires vigorous conditions (200–230 °C) to give the product in a modest yield (49%).1a,1f [2+2] Cycloaddition reactions with alkenes and alkynes occur on the terminal, fluorinated alkene moiety to give ring fluorinated cyclobutane2a and cyclobutene2b derivatives. 1,1-Difluoroallenes also react with various nucleophiles to afford CF₂-terminal or internal addition products selectively, depending on the character of the nucleophile.3

Although the parent 1,1-difluoroallene (CF₂=C=CH₂) has been known since the 1950s,4 very few synthetic methods for 3-substituted 1,1-difluoroallenes have been reported.3a,5 Recently, we have developed a versatile synthetic method for 3-substituted 1,1-difluoroallenes using two steps: (i) lithiation of 1,1-dibromo-2,2-difluoroothene with butyllithium generates 1-bromo-2,2-difluorovinylithium (CF₂=CBrLi), which in turn, reacts with aldehydes or ketones to form 2-bromo-3,3-difluoroallylic acetates, and (ii) treatment of the bromoacetates with butyllithium gives 1,1-difluoroallenes via the 1,2-elimination of lithium acetate.6

However, there are two factors that limit the scope of this method: (a) the starting material, CF₂=CBr₂, is a high-cost, potential ozone-depleting substance, and is now unavailable because of the ban on its industrial manufacture, and (b) the highly nucleophilic alkylithium is required in the preparation of 1,1-difluoroallenes, which restricts the choice of substrate. Here, we report an improved synthetic method for 1,1-difluoroallenes to overcome these issues using (A) an environmentally friendly and commercially available compound as the starting material, and (B) an effective process for carrying out a 1,2-elimination reaction under mild and tolerant reaction conditions.

First, we considered that the key intermediate, a 1-halogenated 2,2-difluorovinyl anion 2 (Scheme 1), would be generated by the addition of two equivalents of a strong base to 1,1,1-trifluoro-2-haloethanes,7–9 which bear two hydrogen atoms and are recognized to have much lower ozone depletion potential (ODP). These compounds are manufactured industrially for use as refrigerants or as fluorinated intermediates. Second, we proposed a different route to access the desired 1,1-difluoroallenes 1 from 3,3-difluoroallylic acetates 3 (Scheme 1) on treatment with a zero-valent metal instead of the highly reactive alkyllithium, which would promote the 1,2-elimination from acetates 3 to form one more double bond under mild conditions. This sequence would expand the scope of the substrates.

Scheme 1  A synthetic plan for 1,1-difluoroallenes from a 1,1,1-trifluoro-2-haloethane

We selected 1,1,1-trifluoro-2-iodoethane as the starting material because of its easy handling (bp. 55–56 °C). The lithiation of 1,1,1-trifluoro-2-iodoethane with two equivalents of LDA at low temperatures (–93 to –85 °C) successfully gave 2,2-difluoroo-1-iodovinylithium (2, Table 1).10 Lithium species 2 then reacted with one equivalent of either an aldehyde or a ketone, and was subsequently acetylated with acetic anhydride (Table 1, Entries 1–8) or with isopropenyl acetate/TsOH (Entry 9) to afford 3,3-difluoro-2-iodoallylic acetates 3 in good yield.

*Acetylation was performed with isopropenyl acetate/TsOH.6*

Then, we found a facile and effective route by the zinc-promoted 1,2-elimination of acetates 3 under mild and tolerant reaction conditions (e.g., at room temperature for several hours) compared with the previously used \( n \)-BuLi-promoted 1,2-elimination.6,11,12 The conditions of the zinc-promoted 1,2-elimination were optimized, as shown in Table 2. In most cases, 1,1-difluoroallenes 1 were obtained in good yield on treatment of acetates 3 with two equivalents of zinc, either in DMF or in THF, at room temperature for 3–12 hours (Table 2, Entries 1–6). However, 1,1-difluoroallene 1g was only formed in DMF, and not in THF (Table 2, Entries 7 and 8), although the reason for this is not clear at present.13 3-Substituted 1,1-difluoroallenes with a primary alkyl group were produced readily using this method, while the yield decreased when the reaction period was extended by several hours (Table 2, Entries 1 and 2). In contrast, the yield of 1,1-difluoroallenes with a secondary or tertiary alkyl group at the 3-position remained steady, even after an extended reaction time (Table 2, Entries 3–5). This may be the result of the stability of 1,1-difluoroallenes.

Owing to the mild conditions of the Zn-promoted 1,2-elimination, 1,1-difluoroallenes bearing a pyridine ring or an ester functionality were synthesized in good yield (Table 1, Entries 7 and 8). A 3,3-disubstituted 1,1-difluoroallene was obtained in high yield from a 1,1-disubstituted 2-iodo-3,3-difluoroallylic acetate, which was prepared from the corresponding ketone (Table 1, Entry 9).

In summary, we have developed a general and efficient method for the synthesis of 1,1-difluoroallenes from commercially available and environmentally friendly 1,1,1-trifluoro-2-iodoethane under mild reaction conditions. This facile and low-cost synthesis allows 1,1-difluoroallenes to be used as practical building blocks for the synthesis of a various useful fluorinated molecules. Their application is in progress in our laboratory and will be reported in due course.

NMR spectra were recorded on Bruker AVANCE-500 or Bruker AVANCE-400 in CDCl3, Chemical shift values were given in ppm relative to internal SiMe4 (for 1H NMR: δ 0.00), CDCl3 (for 13C NMR: δ 77.0), and C6F6 (for 19F NMR: δ 90.2 (d, JCF = 286, 299 Hz), 169.6).

* Allen 1a partly decomposed to a complex mixture.
* Acetate 3g was recovered quantitatively.

To a THF (10 mL) solution of disopropylamine (2.8 mL, 20 mmol) was added butyllithium (12.0 mL, 1.67 M in hexane, 20.0 mmol) over 10 min at 0 °C under argon. The resulting solution was allowed to stir for an additional 15 min, and then cooled to –93 °C using a cold hexane bath. To this cold LDA solution was added a THF (5 mL) solution of CF3-C6H4I (2.10 g, 10.0 mmol) over 10 min, keeping the temperature between –93 °C and –85 °C. After 20 min at the same temperature, a THF (5 mL) solution of 3-phenylpropanol (1.34 g, 10.0 mmol) was added over 5 min, keeping the temperature between –93 °C and –85 °C. The mixture was stirred for an additional 30 min, then warmed to –30 °C over 90 min. After acetic anhydride (1.23 g, 12.0 mmol) was added, the mixture was allowed to warm to 0 °C over 2 h. The reaction was quenched with saturated aqueous ammonium chloride, and the products were extracted with Et2O. The combined organic layers were washed with brine and dried over anhydrous sodium sulfate. After removal of the solvent under reduced pressure, the residue was purified by column chromatography (hexane–AcOEt, 20:1). The acetate 3a was obtained as a colorless liquid (3.01 g, 82%).

(10) The lithiation of CF₃CH₂I with n-BuLi instead of LDA at –93 to –85 °C led to a low yield of 2,2-difluoro-1-iodovinyllithium, probably due to iodine–lithium exchange reaction.

(11) For 2-bromo-3,3-difluoroallylic acetates, zinc-promoted 1,2-elimination also took place readily at room temperature and led to the formation of the corresponding 1,1-difluoroallenes.

(12) Magnesium was employed in THF to promote the 1,2-elimination of acetate 3d in vain.

(13) When THF was used as a solvent, only a trace amount of 1g was observed by the 19F NMR measurement in spite of a large excess amount of zinc and an extended reaction time. A similar behavior was exhibited by some other acetates 3 without a heteroaromatic ring.

Manuscript submission checklist

- Statement of significance of work.
- Full mailing address, telephone, and fax numbers and e-mail address of the corresponding author.
- Graphical abstract.
- 5 key words.
- Original Word file.
- Word file saved as a PDF file.
- Original graphics files.

Send the PDF file, statement of significance of work, and full mailing address, telephone, and fax numbers and e-mail address of the corresponding author to the appropriate Regional Editor. Keep the original Word and graphics files for revisions and for final submission after acceptance.
