Abstract

Cellulosic biomass is available for the production of biofuel, with saccharification of the cell wall being a key process. We investigated whether alteration of arabinofuranosidase in monocots, causes an increase in saccharification efficiency. Arabinofuranosidases have β-1,4-D-xylopyranosyl backbones and 1,3- or 1,4-α-L-arabinofuranosyl residues linked to O-2 and/or O-3 of xylopyranosyl residues as side chains. Arabinoside side chains interrupt the hydrogen bond between arabinofuranosidase and cellulose in the cell wall and carry an ester-linked feruloyl substituent. Arabinose side chains are the base point for xylan and cellulose and carry an ester-linked feruloyl substituent. Arabinose content in the cell wall of transgenic rice plants overexpressing individual ARAF full-length cDNA (OsARAF1-FOX and OsARAF3-FOX) decreased 25% and 20% compared to the control and the amount of glucose increased by 28.2% and 34.2%, respectively. We studied modifications of cell wall polysaccharides at the cellular level by comparing histochemical cellulose staining patterns and immunolocalization patterns using antibodies raised against α-(1,5)-linked l-Ara (LM6) and β-(1,4)-linked d-Xyl (LM10 and LM11) residues. However, they showed no visible phenotype. Our results suggest that the balance between arabinofuranosidase and cellulose might maintain the cell wall network. Moreover, ARAF overexpression in rice effectively leads to an increase in cellulose accumulation and saccharification efficiency, which can be used to produce bioethanol.

Introduction

Biofuel production from lignocellulosic biomass has attracted much attention as a method to reduce the consumption of fossil fuels, but a practical problem for use is that biofuel made from cellulosic biomass is very complex and is difficult to degrade. Therefore, for saccharification, the degradation of cell wall polysaccharides is a key process required to solve this problem.

Primary cell walls mainly consist of three polysaccharides: cellulose, hemicelluloses, and pectin. These polysaccharides determine the cell shape and mechanical strength. Lignin is a phenylpropanoid polymer deposited in the cell wall during secondary wall thickening [1]. Research on cell walls is important not only to understand mechanisms of plant growth and development but also to produce better plant material for practical use. Cell wall matrix polysaccharides generally occupy 10–30% of the dry weight of plants, and hemicellulose is responsible for cross-links between cellulose fibers. The dicot genus and monocot genus except for Commelina have type I cell walls and the hemicelluloses of members are rich in xyloglucan [2], while gramineous monocots have type II cell walls and their hemicellulose is rich in β-1,3,1,4-glucan and arabinogalactan. Arabinogalactan occupies 20–50% of the dry mass of the cell wall in primary and secondary cell walls [3][4]. Arabinogalactans have β-1,4-xylpyranosyl backbone and 1,3- or 1,4-α-L-arabinofuranosyl residues bonded to O-2 and/or O-3 of xylopyranosyl residues as side chains [2][4][5]. The xylan backbone has a 1,4-pyranose structure that is the same as cellulose or β-1,4-glucan, and forms strong hydrogen bonds with the surface of cellulose microfibrils. The arabinose side chain reportedly interrupts this hydrogen bond between arabinogalactan and cellulose, and the ratio of the addition of arabinose side chains to xylan backbone changes the wall mechanical properties [6]. Arabinose side chains can carry an ester-linked feruloyl substituent and these...
feruloyl groups form diferuloyl cross-links between arabinoxylans \[7\]-\[9\], and in secondary cell walls, feruloyl acid is bonded to lignin polymers \[9\]. Thus, the arabinose side chain is the base point for diferuloyl cross-links and lignification. Although arabinoxylanosyl residues are a quantifiably important constituent of plant primary and secondary cell walls, studies on this arabinose as a diferuloyl cross-link base point are lacking.

Genetic modifications of the cell wall have been reported \[10\], and plants with decreased hemicellulose and cellulose are generally physically weak and poorly adapted to the natural environment. For example, the cell wall network containing arabinoxylan has been studied in dicots, and the loss of arabinose was found to be critical for plant development \[11\]. The Arabidopsis double mutant \(tgh1tgh2\) and transgenic UDP-arabinopyranosyl murase RNAi rice plants present lethal or dwarf phenotypes \[12\]-\[13\]. In this paper, we focus on the functions of arabinose residues in arabinoxylan. We modified the arabinose content in rice using arabinoxylanosidase \(ARAF\) overexpressor, Full-length cDNA overexpressor \(FOX\) lines \[14\]-\[15\]. Using the endogenous enzyme may contribute to improved public acceptance of GM crops.

Beyond glycosyl composition analysis, we probed for wall modifications at the cellular level by comparing histochemical cellulose staining patterns and immunolocalization patterns using antibodies raised against \(\alpha\)-(1,5)-linked \(\beta\)-d-Ara (LM6) and \(\beta\)-(1,4)-linked \(\beta\)-d-Xyl (LM10 and LM11) residues. We report the effect of a decrease in arabinose content by \(ARAF\) overexpression on maintenance of the cell wall network through arabinoxylan and cellulose and saccharification efficiency for production of bioethanol.

**Materials and Methods**

**Plant material and growth conditions**

Rice plants of the control \(Oryza sativa\) cv. Nipponbare and the two FOX lines \(AY311\) and \(CO035\), which carry overexpression constructs for \(OaARAF1\) \(RAP\) locus: \(07\)g0686900) and \(OaARAF3\) \((011\)g0131900), respectively, were grown in soil in a greenhouse during the natural growing season. In this environment, the temperature was \(20\)-\(30\)\(^\circ\)\(C\) and the light value was around \(1,000\ \mu\)mol s\(^{-1}\) m\(^{-2}\). All plants retained normal fertility.

The presence of the constructs in genomic DNA of these lines was confirmed by PCR. All experiments were performed with the \(T_2\) generation. Transgenic lines were selected on hygromycin-containing agar plates and tested for heritability of the expression pattern and the altered sugar trait.

**Phylogenetic analysis**

BLAST searches were conducted with amino acid sequences of selected genes, namely \(Oryza sativa\) \((members of GH family 51 and 3\), \(A. thaliana\) \((ARAF1, ARAF2, XYLY1, and XYLY3\), and \(H. vulgare\) \((AXHAI and AXAIII\)). A multiple alignment was generated by the neighbor-joining method in ClustalX \[16\] using full-length sequences and then manually adjusted. The phylogenetic tree was visualized using TreeView \[17\].

**RNA extraction and RT-PCR**

Plant material was frozen in liquid nitrogen and ground with a Tissue Lyser II \((Qiagen, Hilden, Germany)\) according to the manufacturer’s protocol. cDNA was synthesized with ReverTra Ace\(^\oplus\) (Toyobo, Tokyo, Japan) according to the manufacturer’s protocol. For the \(OaARAF1\)-FOX line, the quantity of transcripts was determined using primer sets of \(OaARAF1\)-forward \((5'\)CCAGAAGGGCCAGTTATG-3') and \(OaARAF1\)-reverse \((5'\)CCAGAAGGGCCAGTTATG-3'). For the \(OaARAF3\)-FOX line, the quantity of transcripts was determined using primer sets of \(OaARAF3\)-forward \((5'\)GCCTCTCCTCCTCCTCGTAT-3') and \(OaARAF3\)-reverse \((5'\)CGATACCTGTACAAACCCATACACTCCCT-3'). As an endogenous control, the quantity of \(17S\) rRNA transcript was determined using primer sets of \(17S\) rRNA-forward \((5'\)GCCAATTTACCAATCTCGC-3') and \(17S\) rRNA-reverse \((5'\)CTATGGGCTGAAATCC-3'). The amplified cDNA fragments were separated on \(2\%\) agarose gel and the bands stained with ethidium bromide.

**Enzyme assay**

Enzyme assay in each line was measured according to \[18\]. Mature leaves were frozen in liquid nitrogen and ground with a Tissue Lyser II \((Qiagen, Hilden, Germany)\) at \(30\) Hz for \(2\) min, and the resulted powder washed in \(80\%\) \((v/v)\) EtOH. The supernatant was removed after centrifugation for \(5\) min at \(15,000\ \times g\). The pellet was washed three times with water, three times with methanol:chloroform \((MC = 1:1\) \(v/v)\), and three times with acetone. A drop of phenol:acetic acid:water \((PAW = 2:1:1\) \(v/v/v)\) was added to the pellet and mixed. Two drops of MC were added to the sample and washed with acetone. This process was repeated three times and the sample was then dried at room temperature for over \(1\) h. Starch was removed by digestion with amylase \((2\) unit/ml amylase; Wako, Osaka, Japan) in \(50\) mM sodium acetate buffer \((\text{pH} \ 5.0)\) containing \(1\) \(M\) sodium chloride for \(2\) h. After centrifugation at \(10,000\ \times g\) for \(5\) min, the supernatant was applied to a PD-10 column midi-Trap G-25 \((GE Healthcare, Milwaukee, WI, USA)\) and the eluted fraction was used for the enzyme assay. The concentration of protein was determined by the method of Bradford, with bovine serum albumin as the standard \[19\]. Enzyme activities were determined using a reaction mixture \((200\ \mu\)l) consisting of protein fractions, \(25\) \(mM\) acetate buffer \((\text{pH} \ 5.0)\), and \(1\) \(M\) \(p\)-nitrophenol glycoside. After incubation at \(37\)\(^\circ\)\(C\) for \(30\) min, the reaction was terminated by the addition of \(200\) \(mM\) sodium carbonate \((800\ \mu\)l) and monitored at \(420\) \(nm\). One unit of enzyme activity is defined as \(1\) \(\mu\)mol of \(p\)-nitrophenol liberated per minute at \(37\)\(^\circ\)\(C\) min\(^{-1}\).

**Extraction and analysis of cell wall polysaccharides**

Mature leaves of FOX lines were frozen in liquid nitrogen and ground with a Tissue Lyser II \((Qiagen, Hilden, Germany)\) at \(30\) Hz for \(2\) min, and the resulted powder washed in \(80\%\) \((v/v)\) EtOH. The supernatant was removed after centrifugation for \(5\) min at \(15,000\ \times g\). The pellet was washed three times with water, three times with methanol:chloroform \((MC = 1:1\) \(v/v)\), and three times with acetone. A drop of phenol:acetic acid:water \((PAW = 2:1:1\) \(v/v/v)\) was added to the pellet and mixed. Two drops of MC were added to the sample and washed with acetone. This process was repeated three times and the sample was then dried at room temperature for over \(1\) h. Starch was removed by digestion with amylase \((2\) unit/ml amylase; Wako, Osaka, Japan) in \(50\) mM acetate buffer at \(37\)\(^\circ\)\(C\) for \(3\) h. After reaction, the samples were centrifuged and the residues washed three times with water, MC, and acetone. After washing, the samples were air-dried for over \(12\) h. Alcohol-insoluble residues \((AIRs)\) were used as the cell wall material. A total of \(2\) \(mg\) of AIR was hydrolyzed with \(2\) \(M\) trifluoroacetic acid \((TFA)\) at \(121\)\(^\circ\)\(C\) for \(2\) h. After hydrolysis, the samples were centrifuged at \(15,000\ \times g\) for \(5\) min. The supernatant was the TFA-soluble fraction. The pellets were hydrolyzed with \(72\%\ \text{H}_2\text{SO}_4\) at room temperature for \(2\) h and then diluted to \(4\%\ \text{H}_2\text{SO}_4\) and boiled for \(1\) h. The \(\text{H}_2\text{SO}_4\) solutions were neutralized with \(\text{Ba(OH)}_2\). Sugar in TFA-soluble and -insoluble fractions was treated with methanol:hydrogen chloride and the resulting methyl glycosides were converted into trimethylsilyl \((TMS)\) derivatives and analyzed by gas-liquid chromatography \((GC-14;\ \text{SHI-MADZU}\ Kyoto, Japan)\). Sugar content in TFA-soluble and TFA-insoluble fractions was determined using the phenol sulfuric acid method.
Cellulose analysis

Crystalline cellulose was measured according to [20]. Briefly the samples were treated with acetic and nitric acids to remove non-cellulosic polysaccharides, and the remaining pellets were hydrolyzed with 72% sulfuric acid. Glucose content in sulfuric acid was determined by phenol sulfuric acid method.

Lignin measurement

Lignin contents in each line were measured according to [21]. Explaining briefly, mature leaves were frozen in liquid nitrogen and ground with a Tissue Lyser II (Qiagen, Hilden, Germany) at 30 Hz for 2 min. 3N HCl and 0.1 ml thioglycic acid were added to 20 mg of AIR and heated at 80°C for 3 h. After centrifugation, the pellet was dissolved in 1N NaOH. The solution was submitted to spectrophotometric measurement.

pCA, FA and DFA measurement

Cell wall was treated with 1N NaOH for 12h, and acidified with HCl. pCA, FA and DFA liberated were extracted three time with diethyl ether. The extract was air-dried, then stored in the dark until determination. pCA, FA and DFA contents were determined using HPLC system (Shimadzu, Kyoto, Japan) with a column Luna C18(2) column, (150x4.60mm, Phenomenex, USA) and monitored for UV(262 nm) and fluorescence (330 and 435 nm). The column equilibrated with 5 mM ammonium acetate (pH 4.4) containing 25% methanol was eluted by a linear gradient of methanol (25–50%, 2–10 min) and 5 mM ammonium acetate (pH 4.4) containing 50% methanol (10–20 min) at flow rate of 1.0 ml/min.

Immunohistochemistry and cellulose staining

To perform immunolocalization, leaves of the control, OsARAF-FOX, and OsARAF3-FOX lines at the same development stage were fixed with 4% paraformaldehyde, 0.25% glutaraldehyde, and 0.05 M phosphate buffer (pH 7.5) and embedded in 5% agar. Sections of 30 µm were cut with a microtome (VT1200S; Leica Microsystems, Nussloch, Germany). The TSATM Kit no. 12, with HRP-goat anti-rabbit IgG and Alexa Fluor 488 tyramide (Molecular Probes/Invitrogen, Eugene, OR, USA), was used according to the manufacturer's protocol. The primary antibodies LM6, LM10, and LM11 (PlantProbes, Hilden, Germany) at 30 Hz for 2 min. An aliquot of 1.2 ml of 0.1 M sodium acetate buffer (pH 4.5) was added to 40 mg of the resulting powder and suspended. A sample of 60 µl was recovered and 40 µl sodium acetate buffer added at time 0. A total of 10 mg/ml Meiselasẽ (Meiji, Tokyo, Japan) was added to the remaining sample and reacted at 45°C with shaking at 120 Hz. After 1–24 h, 100 µl suspensions were recovered followed by centrifugation at 15,000 x g for 10 min at room temperature. Sugar content in the supernatant was determined by the phenol sulfuric acid method. The saccharification efficiency was calculated as sugar liberation (%) = µg/mg dry weight of leaves.

Results

Selection of ARAF genes from the FOX library

To select the ARAF genes of rice, we searched the Rice PIPELINE database (http://cdna01.dna.affrc.go.jp/PIPE/; [22]) and identified 16 putative ARAF genes with reference to the Carbohydrate-Active enzyme [CAZy] database (http://www.cazy.org; [23] [24]), showing that the ARAF genes are members of GH family 3 and 51. We generated a phylogenetic tree using 16 rice ARAF genes, four Arabidopsis thaliana genes (ARAF1: At3g10740, ARAF2: At5g26120, XLY1: At1g49360, XLY3: At5g09730), and two Hordeum vulgare genes (AXHAI and AXAHII). Several enzymes of the GH family 3 and 51 have been reported to have bifunctional activity for ARAF/β-o-xylbiosidase. Arabidopsis XLY1 and XLY3 [25][26] have activity to hydrolyze p-nitrophenyl-β-L-arabinofuranoside (PNP-ARAf), p-nitrophenyl-β-o-xylpyranoside (PNP-Xyl), oat spelt xylan, wheat arabinoxylan, and oligoarabinoxylan [25]. ASD1 and ASD2 have only ARAF activity [27]. The barley AXAH-I and AXAH-II have ARAF activity to release arabinose from 1,3-O-arabinopentose, sugar beet arabinan, wheat arabinoxylan, and larchwood (Larix) arabinogalactan, but do not release d-Xyl [28][29]. The phylogenetic tree showed that enzymes belonging to GH family 3 have bifunctional activity for ARAF/β-o-xylbiosidase and those in GH family 51 seemed to only have ARAF activity (Figure 1A). Therefore, we selected genes from GH family 51 for further study.

For a systematic approach to analyze a gain-of-function phenotype, [14][15] developed the FOX hunting system by using expression libraries for full-length cDNAs (fl-cDNAs) from rice at a maximum of 28,000 fl-cDNAs clones in total, and individually overexpressed the fl-cDNAs in rice driven by the maize Ubiquitin-1 gene promoter. Among ~14,500 FOX-rice lines, we identified two lines overexpressing fl-cDNAs for OsARAF1 (Accession no. AK064838, Rap-Id:Os07g0686900), and OsARAF3 (AK065240, Os11g0131900) in GH family 51 and named them the OsARAF1-FOX and OsARAF3-FOX lines. We analyzed a total of 23 plants from the T1 to T3 generations; they showed essentially identical results. Since OsARAF3 has high homology to H. vulgare ARAF AXAHII and AXAHIII [23], OsARAF3 was expected to cleave various arabinofuranosyl side chains, e.g., arabinoxylan and rhamnogalacturonan-I (RG-I).

The expression levels and patterns in OsARAF1 and OsARAF3 of leaf, stem, and root of immature seedlings (14 days old) and leaf and stem of mature plants (60 days old) were analyzed by reverse transcription (RT)-PCR expression analysis (Figure 1B). OsARAF1 was expressed strongly in 14- and 60-day-old stems but was not detectable in 14+ and 60-day-old leaves. OsARAF3 was expressed weakly in 14- and 60-day-old leaves. These results are consistent with data retrieved from the RiceXPro (http://ricexpro.dna.affrc.go.jp; [30]). Because OsARAF1 and OsARAF3 are not expressed or only expressed weakly in leaves, we focused on their effects on leaves.

Measurement of mechanical properties

Mature leaves of 7–8 mm width of the control, OsARAF1-FOX, and OsARAF3-FOX were cut 12 cm from the leaf tip and immediately used to assess mechanical properties. Both sides of a sample were adhered to the stage, with an interval of 2 cm; the stage moved to load the middle of the sample on the sensor; and the measurement of mechanical properties was performed without the primary antibody. The TSATM Kit no. 12, with HRP-goat anti-rabbit IgG and Alexa Fluor 488 tyramide (Molecular Probes/Invitrogen, Eugene, OR, USA), was used according to the manufacturer's protocol. The primary antibodies LM6, LM10, and LM11 (PlantProbes, Hilden, Germany) were cut with a microtome (VT1200S; Leica Microsystems, Nussloch, Germany). The TSATM Kit no. 12, with HRP-goat anti-rabbit IgG and Alexa Fluor 488 tyramide (Molecular Probes/Invitrogen, Eugene, OR, USA), was used according to the manufacturer's protocol. The primary antibodies LM6, LM10, and LM11 (PlantProbes, Leeds, UK) were used at 1:30 dilution. HRP conjugate working solution was used at a 1:100 dilution. A negative control experiment was performed without the primary antibody. Cellulose was stained with 0.01% calcofluor white (Fluorescent Brightener 28; Sigma-Aldrich, St. Louis, MO, USA). All sections were observed using fluorescence microscopy (Leica Microsystems, Wetzlar, Germany), with UV filter A, excitation filter BP 340–380 nm, suppression filter LP 425, and an exposure time of 190 ms.

Measurement of saccharification efficiency

Mature leaves were ground with a Tissue Lyser II (Qiagen, Hilden, Germany) at 30 Hz for 2 min. An aliquot of 1.2 ml of
OsARAF1-FOX and OsARAF3-FOX lines were ARAF overexpressors. RT-PCR analysis showed that OsARAF1 and OsARAF3 transcripts were elevated in OsARAF1-FOX and OsARAF3-FOX, respectively (Figure 2A). ARAF activity in mature leaves, assayed using \( p \)-nitrophenyl arabinofuranoside as substrate, increased 1.7-fold in OsARAF1-FOX and OsARAF3-FOX compared to the control (Figure 2B and Figure S1A). Since some ARAFs have bifunctional activity for ARAF/\( \beta \)-D-xylosidase, we measured xylosidase activity using \( p \)-nitrophenyl xyloside as substrate. The xylosidase activities in OsARAF1-FOX and OsARAF3-FOX lines were almost the same as in the control (Figure 2C and Figure S1B), as predicted from the phylogenetic analysis.

OsARAF1-FOX and OsARAF3-FOX lines, however, showed no visible phenotype (Figure 3). Vegetative parameters, plant height, stem diameter, and number of tillers, and reproductive parameters, fertility rate, number of rachis-branches, and spike length, were unchanged in OsARAF1-FOX and OsARAF3-FOX lines compared to the control (data not shown). Two FOX lines did not show high lodging.

Effects of overexpression of ARAF on cell wall composition

We determined the glycosyl composition of cell walls prepared from mature leaves of OsARAF1 and OsARAF3 lines. The
Overexpression of Arabinofuranosidase in Rice

Glycosyl composition analysis and histochemical observation showed that overexpression of ARAF caused a decrease in arabinose and xylose content and an increase in cellulosic glucose in the cell wall. The altered cell wall composition may influence plant mechanical properties, and thus we examined differences in mechanical properties between the control, OsARA1-FOX, and OsARA3-FOX leaves using the creep meter test. The breaking force and extension of leaves was similar among the control, OsARA1-FOX, and OsARA3-FOX lines (Table 1, Table 2 and Figure 4C).

Overexpression of ARAF caused changes in localization of cell wall components

We further determined the distribution of cell wall sugars using monoclonal antibodies against cell wall polysaccharide epitopes and Calcofluor White. The monoclonal antibody LM6 labels arabinan and arabinoxylan side chains in arabinoxylan epitopes ([31]; University of Georgia: http://www.ccrc.uga.edu/mao/wallmab/ Antibodies/antib.htm). LM11 labeled the arabinoxylan and LM10 labeled the xylan epitope [32]. When probed with LM6, OsARA1 and OsARA3 had fewer signals in all tissues (Figure 5D–F). Moreover, LM11 stained the wall of vascular bundles and the epidermis of the control, but few signals were detected in OsARA1 and OsARA3 lines (Figure 5G–I). However, LM10 label had the same signal intensity among the control, OsARA1-FOX, and OsARA3-FOX lines (Figure 5J–L).

In OsARA1 and OsARA3, a high intensity of Calcofluor staining was observed in the midrib and phloem (Figure 6D–F). Calcofluor White is reported to stain β-1, 4-glucan (cellulose), β-1, 3-glucan (callose), and mannan [33][34]. Because callose is present in specific cell wall components [33], and the resulting glycosyl composition showed very little mannan (Table 1 and Table 2), Calcofluor White should stain cellulose.

Overexpression of ARAF affects the improvement of mechanical strength

Glycosyl composition analysis and histochemical observation showed that overexpression of ARAF caused a decrease in arabinoxylose and xylose content and an increase in cellulosic glucose in the cell wall. The altered cell wall composition may influence plant mechanical properties, and thus we examined differences in mechanical properties between the control, OsARA1-FOX, and OsARA3-FOX leaves using the creep meter test. The breaking force and extension of leaves was similar among the control, OsARA1-FOX, and OsARA3-FOX. The extension length was slightly increased in OsARA3-FOX (Figure 7). These results

indicate that overexpression of ARAF may affect the improvement of mechanical properties of the leaf.

Overexpression of ARAF led to an increase in saccharification efficiency

The increase in cellulosic glucose content in the cell wall of OsARAF1-FOX and OsARAF3-FOX lines implied that FOX lines produce more glucose in saccharification compared to the control. We measured sugar liberation from OsARAF1-FOX and OsARAF3-FOX mature leaves (Figure 8A and B). The rates of saccharification were almost the same for 1 h in the control, but
Figure 7. Mechanical properties of leaves of the control, OsARAF1-FOX and OsARAF3-FOX lines. The break force is expressed per leaf width. The horizontal axis shows the extension length. Black, white and gray symbols indicate the control, OsARAF1-FOX and OsARAF3-FOX, respectively. Error bars indicate the SD (n=8).

Discussion

We analyzed ARAF-overexpressed rice plants. Arabinose content in the cell walls of the two ARAF-overexpressed plants decreased to 75% and 80% of that in the control, and the amount of cellulose glucose increased to 128.2% and 134.2% of that of control. We did not use fungal ARAF for which the exact activity against multiple substrates is known because overexpression of fungal ARAF might have resulted in lethal due to xylan degradation and inhibition of cell wall synthesis. The use of fungal cell wall hydrolases was previously shown to result in a low yield [36]; therefore, we used the endogenous arabinoarufanosidases. OsARAF1-FOX and OsARAF3-FOX showed no morphological phenotype and some improvement of mechanical strength as the control (Figure 3 and 7). In addition, overexpression caused an increase in saccharification efficiency (Figure 8).

Arabinoxylans are major non-cellulosic polysaccharides in primary and secondary walls of grass cell walls. They are hydrogen-bonded to themselves and cellulose microfibrils to form cellulose–hemicellulose networks. Ferulic acids are ester-linked to arabinose side chains of arabinoxylan to form diferulate cross-linked arabinoylan. In monocots, most arabinose residues exist as side chains of arabinoylan. In secondary cell walls, ester-linked ferulic acid is incorporated into lignin to form an arabinoylan–lignin complex [9]. Hence, arabinose residues are thought to be the base point for cross-linking between arabinoxylan and lignin [37]. In growing tissues, arabinoylan content in cell walls increases slowly and arabinoxylans are highly branched with arabinosyl residues and are removed during growth [38][39].

ARAFs are defined as enzymes that catalyze the hydrolysis of terminal, nonreducing α-L-arabinofuranose residues. However, several enzymes in family 51 are capable of hydrolyzing both L-Ara and β-D-Xyl from a variety of substrates in vitro, and therefore may be considered as bifunctional ARAF/β-D-xylosidase enzymes.

Figure 8. Saccharification of the control OsARAF1-FOX and OsARAF3-FOX lines in dry leaves. Time-dependent saccharification (A) and saccharification efficiency after 24 h (B) were measured. Error bars indicate the SD (n=3). Black, white and gray columns indicate the control, OsARAF1-FOX and OsARAF3-FOX, respectively. Different letters in the same column indicate significant differences at P<0.05 (Tukey’s test).

For example, barley ARA-I, Arabidopsis XYL1 and ARAF1, and alfalfa MsXyl1 have bifunctional enzyme activity [25][26][40][41]. However, our results showed that OsARAF1 and OsARAF3 may have only ARAF activity and no xylosidase activity (Figure 2B and C). And, lignin complexes with arabinoylan are mediated by ferulic acid [9]. In OsARAF1-FOX and OsARAF3-FOX, the amounts of ferulic acid were similar to that in the control. These results suggest that OsARAF1 and OsARAF3 do not possess the ability to cleave the linkage of the arabinose residue to ferulic acid. Expression of OsARAF1 and OsARAF3 was higher in growing organs and lower in mature organs (Figure 1B). These results indicate that arabinoylans are turned over during cell wall development in growing organs.

Arabinose residues are a quantifiably important constituent in various cell wall components, not only arabinoylan but pectin RG-I and glycoprotein [2][42]. Glycosyl composition analysis of cell walls and immunohistochemistry showed that arabinoylan residues in arabinoylans decreased in OsARAF1-FOX and OsARAF3-FOX lines. The xylan in OsARAF1-FOX and OsARAF3-FOX also decreased in the hemicellulose fraction (Table 1). This result suggests that the xylan main chain decreases by reducing the side chain arabinose in FOX lines. The ratios of arabinose to xylose in OsARAF1-FOX and OsARAF3-FOX were 1:3, the same as that in the control (Table 1). These results indicate that a change occurred in the quantity rather than the structure of.
Overexpression of Arabinofuranosidase in Rice

arabinofuranosidase in the FOX lines as compared to the control. The amounts of arabinose side chains may influence the xylan backbone extension, and arabinose residues may be important in the formation of the cell wall network. On the other hand, overexpression of AtARAF1 leads to increases in the secondary cell wall, especially xylan [45]. In any case, arabinofuranosidase overexpression may cause modification of the secondary cell wall.

Neither OsARAF1-FOX nor OsARAF3-FOX affected plant growth (Figure 3). The increase in cellulose may compensate for the reduction in arabinosylxylan (Table 1, Table 2 and Figure 6). Additionally, amount of crystalic cellulose in OsARAF3-FOX increased compared to the control (Figure 4A). Staining with Calcofluor White increased in the midrib and phloem of FOX lines, which is associated with the increased mechanical strength (Figure 6D–F and Figure 7). From these results, it appears that rice might maintain plant body strength by maintaining a balance between cellulose and hemicellulose. In fact, OsARAF1-FOX and OsARAR3-FOX lines showed slightly increase of mechanical strength compared to the control (Figure 7). In dicots, xylouglucan is hydrogen-bonded to cellulose microfibrils. In xyloglucanase-overexpressed poplar, the amount of cellulose increased [44] and led to the generation of abnormal tensile stress. In this study, ARAF-overexpressed rice had a lower arabinosylxylan content, and so it was expected to have a similar phenotype; however, no influence on growth occurred (Figure 3). Unlike dicots, rice has interspersed vascular bundles, which have less influence on retaining the strength of the plant body, so an increase of cellulose may have a positive effect on growth.

OsARAF1-FOX and OsARAF3-FOX lines had increased saccharification efficiency (Figure 8A and B). In industrial processes, plant biomass is treated with hemicellulose and cellulose because cellulose covers the cell wall matrix. We expected that the increased saccharification efficiency of FOX lines would depend on decreases in hemicellulose and substituted xylan [45]. The saccharification efficiency after 24 h reaction increased in FOX lines (Figure 8A), which may have been caused not only by an increase in accessibility of the cellulose due to a decrease in hemicelluloses but also an increase in cellulose content. In cell walls, glucose is contained in cellulose and β-1,3-1,4-glucan. The hydrolysis of β-1,3-1,4-glucan is accelerated by growth regulators; in mature leaves, the β-1,3-1,4-glucan level is low [2]. The amount of lignin increased slightly in OsARAF1-FOX and OsARAF3-FOX lines, but this didn’t influence saccharification efficiency. Lignin complexes with arabinoxylan and is mediated by ferulic acid [9]. In this study, the decrease in arabinofuranosyl had little effect on cell wall network assembly and growth. The small change in cell wall components led to higher cellulose content in the plant but had no effect on growth. And, in previous studies, few examples of increases in cellulose content in cell walls were reported. Hence, our report provides an important contribution to the study of cell wall biosynthesis and future technology. The modification cell walls in rice through ARAF overexpression improves saccharification efficiency, and these FOX rice lines could prove useful for producingcellulosic bioethanol.

Supporting Information

Figure S1 Enzyme activity in WT, OsARAF1-FOX and OsARAF3-FOX. (A) ARAF activity using 4-nitrophenyl-α-L-arabinofuranoside as substrate in WT, OsARAF1-FOX and OsARAF3-FOX leaves. (B) Xylosidase activity using 4-nitrophenyl-β-D-xylopyranoside as substrate in WT, OsARAF1-FOX and OsARAF3-FOX leaves. Black, white, and gray columns indicate the WT, OsARAF1-FOX, and OsARAF3-FOX lines, respectively. Black, white, and gray columns indicate WT, OsARAF1-FOX, and OsARAF3-FOX, respectively. (PDF)
