### Abstract

The long time asymptotics of the time spent on the positive side are discussed for one-dimensional diffusion processes in random environments. The limiting distributions under the log-log scale are obtained for the diffusion processes in the stable medium as well as for the Brox model. Similar problems are discussed for random walks in random environments and it is proved that the limiting laws are the same as in the case of diffusions.

# 1 Introduction.

In this paper, we are concerned with the long time asymptotics of the occupation times on the positive side

$$A(n) = \sum_{i=1}^{n} 1_{\{Z(i-1) \ge 0, Z(i) \ge 0\}}, \quad n = 1, 2, \dots$$
 and

$$A(t) = \int_{0}^{t} \mathbb{1}_{[0,\infty)}(X(s)) \, ds, \quad t \ge 0 \tag{1}$$

for a class of one-dimensional random walks  $\mathbf{Z} = (Z(n))$  on  $\mathbb{Z}$  and diffusion processes  $\mathbf{X} = (X(t))$  on  $\mathbb{R}$ , respectively, in random environments. For a better understanding of the problem and results, we would review some recent studies in the case of usual generalized diffusions on the real line.

Let  $X = (X(t), P_x)$  be a one-dimensional (generalized) diffusion process on  $\mathbb{R}$ with the Feller generator  $\mathcal{L} = \frac{d}{dm} \frac{d}{ds}$ . Here,  $s : x \in \mathbb{R} \mapsto s(x) \in \mathbb{R}$  is a strictly increasing continuous function such that s(0) = 0 and  $\lim_{x \to \pm \infty} s(x) = \pm \infty$ and dm(x) is a non-zero positive Radon measure on  $\mathbb{R}$ . The state space of X is the support of the measure dm so that X is a birth and death process when dm is supported on the one-dimensional lattice  $\mathbb{Z}$ . Note that X is always conservative and recurrent. For the occupation time (1), the class of possible limit random variables in law of A(t)/t as  $t \to \infty$  coincides with the class of Lamperti random variables  $\{Y_{p,\alpha}\}_{0 \le p \le 1, 0 \le \alpha \le 1}$ :  $Y_{p,\alpha}$  is a [0, 1]-valued random variable with the Stieltjes transform

$$E\left(\frac{1}{\lambda+Y_{p,\alpha}}\right) = \frac{p(\lambda+1)^{\alpha-1} + (1-p)\lambda^{\alpha-1}}{p(\lambda+1)^{\alpha} + (1-p)\lambda^{\alpha}}, \qquad \lambda > 0.$$

Also, a sufficient condition, which turns out to be necessary and sufficient when 0 , can be given in terms of <math>s(x) and dm(x) for the convergence

$$\frac{1}{t}A(t) \xrightarrow{d} Y_{p,\alpha} \quad \text{as} \quad t \to \infty$$
(2)

to hold (cf. [15]).

When  $\alpha = 1$ ,  $Y_{p,1}$  is a constant random variable;  $P(Y_{p,1} = p) = 1$  so that (2) is a law of large numbers. We have studied in [10] some improvements such as behaviors of fluctuations  $\frac{1}{t}A(t) - p$  for these laws of large numbers.

When  $\alpha = 0$ , the limit random variable  $Y_{p,0}$  is a Bernoulli random variable;  $P(Y_{p,0} = 1) = 1 - P(Y_{p,0} = 0) = p$ . The convergence (2) in this case occurs when X is recurrent but is *nearly transient*, or in other words, is *apt to localize*. We have studied in [9] its improvement in the log-log scale: For example, for the diffusion  $X = (X(t), P_x)$  with generator

$$\mathcal{L} = \frac{1}{2} \left( \frac{d^2}{dx^2} + \frac{x}{1+x^2} \frac{d}{dx} \right) \quad \text{on } \mathbb{R},$$

the asymptotic (2) holds with the limit random variable  $Y_{\frac{1}{2},0}$  (under  $P_x$  for

any but fixed x) and it can be improved as

$$\frac{1}{\log t} \log A(t) \xrightarrow{d} U, \quad \text{as} \quad t \to \infty$$
(3)

where U is a [0, 1]-valued random variable with P(U < 1) = P(U = 1) = 1/2; actually, in this case, the law of U is given by

$$\frac{1}{(1+x)^2} \mathbb{1}_{\{0 \le x < 1\}} dx + \frac{1}{2} \,\delta_{\{1\}}(dx),\tag{4}$$

#### (cf. [9], Example 1).

It is in this case of  $\alpha = 0$  that we can see some similarity with a diffusion process in a random environment because of its localization character. In this model, we cannot expect the convergence (2) to a Bernoulli random variable if the environment is frozen; i.e., in the *quenched* model. However, for the *annealed* model in which we average on the environments, the convergence (2) to a Bernoulli random variable actually takes place. We can further obtain its improvement in the log-log scale. For example, in the Brox model (cf. [5]) which is given as  $\mathcal{L}^w = \frac{1}{2} e^{w(x)} \frac{d}{dx} \left( e^{-w(x)} \frac{d}{dx} \right)$ -diffusion  $X^w = (X^w(t), P_x^w)$ on  $\mathbb{R}$  for a given Brownian path w(x), we have that, under the annealed probability  $\overline{P}_0(\cdot) = \int P_x^w(\cdot) P(dw)$ , P(dw) being the Wiener measure over the paths  $w : x \in \mathbb{R} \mapsto w(x) \in \mathbb{R}$ , the convergence (2) holds to the Bernoulli random variable  $Y_{\frac{1}{2},0}$  and its improvement in the log-log scale is given in the same way as (3) where U is a [0, 1]-valued random variable with its law given by  $\frac{1}{2} \mathbb{1}_{\{0 \le x \le 1\}} dx + \frac{1}{2} \delta_{\{1\}}(dx)$ . This can be obtained as a particular and typical example of results in Theorems 20 and 23 given in Section 4 below.

Finally, we summarize the contents of this paper. In Section 2, we develop a general theory for the growth in time, in the log scale, of a class of onedimensional Brownian additive functionals. In Section 3, the results in Section 2 will be applied to obtain general results on asymptotic growth in time, in the log scale, of occupation times on the positive side of a family of onedimensional diffusion processes depending on a parameter  $\lambda > 0$ . In Section 4, we discuss the long time asymptotics of occupation times on the positive side for diffusions and random walks in random environments by appealing to the general results in Section 3. Here, the scaling property, i.e., a self-similarity, is essential in reducing the problem to results obtained in Section 3, so that we fundamentally assume that the environment is self-similar in the case of diffusions and is asymptotically self-similar in the case of random walks. Our model in Subsection 4.1 is a particular case of models introduced and studied by Y. Suzuki [14]; the environments on the positive and the negative side are mutually independent symmetric stable processes which may have different exponents. The case of random walks will be studied in Subsection 4.2 by imbedding them in birth and death processes with asymptotically self-similar environments (cf. Kawazu-Tamura-Tanaka [11], Hu-Zhan [6]).

### 2 Asymptotics of a family of Brownian additive functionals.

In this section, we prepare some results on long time asymptotics of a family of increasing Brownian additive functionals parametrized by  $\lambda > 0$ . These results will be a basic tool to obtain results on occupation times for random walks and diffusions in random environments in Section 4. Before proceeding, we set up a general framework.

Let  $\Phi$  be the set of all càdlàg nondecreasing functions  $\varphi : [0, \infty) \ni x \mapsto \varphi(x) \in [0, \infty)$ . We set always  $\varphi(0-) = 0$  for  $\varphi \in \Phi$ . We identify  $\varphi$  with its associated Lebesgue-Stieltjes measure  $d\varphi$ , which is the positive Radon measure on  $[0, \infty)$  such that  $(d\varphi)([0, a]) = \varphi(a)$ ,  $a \in [0, \infty)$ . For  $\varphi_{\lambda}, \varphi \in \Phi$ , we define  $\varphi_{\lambda} \to \varphi$  in  $\Phi$  as  $\lambda \to \infty$ , or denote it as  $\lim_{\lambda \to \infty} \varphi_{\lambda} = \varphi$ , if  $\lim_{\lambda \to \infty} \varphi_{\lambda}(x) = \varphi(x)$  for every  $x \in [0, \infty)$  such that  $\varphi(x) = \varphi(x-)$ , equivalently, for every x in a dense subset of  $[0, \infty)$ . This definition can also be stated as follows:  $\lim_{\lambda \to \infty} \varphi_{\lambda} = \varphi$  in  $\Phi$  if and only if; for every  $x \in [0, \infty)$ ,

$$\varphi(x-) \le \liminf_{\lambda \to \infty} \varphi_{\lambda}(x-) \le \limsup_{\lambda \to \infty} \varphi_{\lambda}(x) \le \varphi(x).$$
(5)

As is well-known,  $\varphi_{\lambda} \to \varphi$  in  $\Phi$  as  $\lambda \to \infty$  if and only if

$$\lim_{\lambda \to \infty} \int_{[0,\infty)} f(x) \, d\varphi_{\lambda}(x) = \int_{[0,\infty)} f(x) \, d\varphi(x)$$

for every continuous function f on  $[0, \infty)$  with a compact support. The composite  $\varphi \circ \psi$ , for  $\varphi, \psi \in \Phi$ , is defined as usual by  $\varphi \circ \psi(x) = \varphi(\psi(x)), x \in [0, \infty)$ . It does *not* hold, in general, that  $\varphi_{\lambda} \to \varphi$  and  $\psi_{\lambda} \to \psi$  in  $\Phi$  imply  $\varphi_{\lambda} \circ \psi_{\lambda} \to \varphi \circ \psi$  in  $\Phi$ . We can, however, deduce from (5) that  $\varphi_{\lambda} \to \varphi$  and  $\psi_{\lambda} \to \psi$  in  $\Phi$  imply the following:

$$\lim_{\lambda \to \infty} \varphi_{\lambda}(\psi_{\lambda}(x)) = \varphi(\psi(x))$$
  
for every  $x \in [0, \infty)$  such that  $\varphi(\psi(x-)) = \varphi(\psi(x)).$  (6)

Thus we have

**Lemma 1** Let  $\varphi_{\lambda}, \varphi, \psi_{\lambda}, \psi \in \Phi$ . If  $\varphi_{\lambda} \to \varphi$  and  $\psi_{\lambda} \to \psi$  in  $\Phi$  and if the set  $\{x > 0 \mid \varphi(\psi(x-)-) = \varphi(\psi(x))\}$  is dense in  $[0,\infty)$ , then  $\varphi_{\lambda} \circ \psi_{\lambda} \to \varphi \circ \psi$  in  $\Phi$ .

It is well-known that there exits a metric  $\rho$  on  $\Phi$  such that  $\Phi$  is a Lusin space (a standard measurable space, i.e., a Borel subset of a Polish space with the relative topology, cf. [3] or [13]) and, for  $\varphi_{\lambda}, \varphi \in \Phi, \varphi_{\lambda} \to \varphi$  in  $\Phi$  is equivalent to  $\lim_{\lambda \to \infty} \rho(\varphi_{\lambda}, \varphi) = 0$ .

Let

$$\Phi_{\infty} = \{ \varphi \in \Phi \mid \lim_{x \to \infty} \varphi(x) = \infty \}.$$

 $\Phi_{\infty}$  is a Borel subset of  $\Phi$ . For  $\varphi \in \Phi_{\infty}$ , we define the right-continuous inverse  $\varphi^{-1} \in \Phi_{\infty}$  by

$$\varphi^{-1}(x) = \inf\{y > 0 \mid \varphi(y) > x\}, \quad x \in [0, \infty).$$

It is easy to see that  $(\varphi^{-1})^{-1} = \varphi$  for any  $\varphi \in \Phi_{\infty}$  and,  $(\psi \circ \varphi)^{-1} = \varphi^{-1} \circ \psi^{-1}$ if  $D(\varphi^{-1}) \cap D(\psi) = \emptyset$ , where

$$D(\varphi) = \{ x \in [0, \infty) \mid \varphi(x) \neq \varphi(x-) \}.$$

Also, it holds that, for  $\varphi_{\lambda}, \varphi \in \Phi_{\infty}$ ,

$$\varphi_{\lambda} \to \varphi \quad \text{in } \Phi \quad \text{if and only if} \quad \varphi_{\lambda}^{-1} \to \varphi^{-1} \text{ in } \Phi$$

$$\tag{7}$$

We introduce the following notation: For  $\lambda > 0$ ,  $e_{\lambda} \in \Phi_{\infty}$  is defined by

$$e_{\lambda}(x) = e^{\lambda x} - 1, \quad x \in [0, \infty).$$
(8)

Thus,

$$e_{\lambda}^{-1}(x) = \frac{1}{\lambda}\log(x+1), \quad x \in [0,\infty).$$
 (9)

Now we consider  $\Phi$ -valued random variables. Since  $\Phi$  is a Lusin space so that  $\Phi$  is a Borel subset of a Polish space  $\tilde{\Phi}$ , a  $\Phi$ -valued random variable can be identified with a  $\tilde{\Phi}$ -valued random variable. Thus  $\Phi$ -valued random variables may be regarded as random variables with values in a Polish space.

For  $\Phi$ -valued random variables  $X_{\lambda}, \lambda > 0$  and  $X, X_{\lambda} \xrightarrow{d} X$  as  $\lambda \to \infty$ denotes the *convergence in law*, that is, the law on  $\Phi$  of  $X_{\lambda}$  converges in the weak (or *narrow* in the terminology of [4]) topology to the law on  $\Phi$  of X. Also,  $X_{\lambda} \xrightarrow{p} X$  denotes the *convergence in probability*, that is,  $P(\rho(X_{\lambda}, X) > \epsilon) \to 0$  as  $\lambda \to \infty$  for every  $\epsilon > 0$ . Similarly,  $X_{\lambda} \longrightarrow X$ , a.s. denotes the *almost-sure convergence*, that is,  $P(\rho(X_{\lambda}, X) \to 0 \text{ as } \lambda \to \infty) = 1$ .

The following implication is well-known:

$$X_{\lambda} \longrightarrow X, a.s. \Rightarrow X_{\lambda} \xrightarrow{p} X \Rightarrow X_{\lambda} \xrightarrow{d} X.$$

Conversely, the following Skorohod realization theorem (cf. [7], p.9) holds: If  $X_{\lambda} \xrightarrow{d} X$  as  $\lambda \to \infty$ , then we can realize  $\widetilde{X}_{\lambda}$  and  $\widetilde{X}$  on a suitable probability space in such a way that  $\widetilde{X}_{\lambda} \stackrel{d}{=} X_{\lambda}$  for each  $\lambda > 0$ ,  $\widetilde{X} \stackrel{d}{=} X$  and  $\widetilde{X}_{\lambda} \longrightarrow \widetilde{X}$ , *a.s.*, as  $\lambda \to \infty$ . Therefore, problems on the convergence in law may be reduced to the discussions on almost-sure convergence. Note also that  $X_{\lambda} \stackrel{d}{\to} X$  implies  $X_{\lambda}(x) \stackrel{d}{\to} X(x)$  for each x such that P(X(x) = X(x-)) = 1.

The proof of the following Proposition is easy and omitted.

**Proposition 2** (i) If X is a deterministic  $\Phi$ -valued random variable so that  $X \equiv \varphi$  for some  $\varphi \in \Phi$ , then  $X_{\lambda} \xrightarrow{d} X$  as  $\lambda \to \infty$  if and only if  $X_{\lambda} \xrightarrow{p} X$  as  $\lambda \to \infty$ .

(ii) For a fixed  $\varphi \in \Phi$ ,  $X_{\lambda} \xrightarrow{p} \varphi$  as  $\lambda \to \infty$  if and only if, for every  $x \in [0, \infty)$  such that  $\varphi(x) = \varphi(x-)$  (equivalently, for every x in a dense subset of  $[0, \infty)$ ),  $X_{\lambda}(x) \xrightarrow{p} \varphi(x)$  as  $\lambda \to \infty$  as real random variables.

Let B = (B(t)) be  $BM^0(\mathbb{R})$ ; a one-dimensional standard Brownian motion starting at 0 and  $\{\ell(t, x); t \ge 0, x \in \mathbb{R}\}$  be the local time of B with respect to the measure 2 dx:

$$\int_{0}^{t} 1_{E}(B(s)) \, ds = 2 \int_{E} \ell(t, x) \, dx, \quad E \in \mathcal{B}(\mathbb{R}).$$

Suppose we are given  $\widetilde{m}_{\lambda} = (\widetilde{m}_{\lambda}(x)) \in \Phi$  for each  $\lambda > 0$ . Define a  $\Phi$ -valued random variables  $S_{\lambda}$  by

$$S_{\lambda}(t) = \int_{[0,\infty)} \ell(t,x) \, d\widetilde{m}_{\lambda}(x), \quad t \ge 0.$$
<sup>(10)</sup>

**Lemma 3** Assume that, for some  $c = (c(x)) \in \Phi$ ,

$$e_{\lambda}^{-1} \circ \widetilde{m}_{\lambda} \circ e_{\lambda} \longrightarrow c \quad in \ \Phi \quad as \ \lambda \to \infty.$$
 (11)

Then

$$e_{\lambda}^{-1} \circ S_{\lambda} \circ e_{2\lambda} \xrightarrow{p} \xi \quad in \ \Phi \quad as \ \lambda \to \infty,$$
 (12)

where  $\xi \in \Phi$  (deterministic) is defined by

$$\xi(t) = t + c(t), \quad t \ge 0.$$
 (13)

**Proof.** By Proposition 2 (ii), it is sufficient to show that, for any  $t \in [0, \infty)$ 

such that  $\xi(t) = \xi(t-)$ ,

$$\frac{1}{\lambda}\log\{S_{\lambda}(e^{2\lambda t}-1)+1\} \xrightarrow{p} \xi(t) \quad as \ \lambda \to \infty.$$
(14)

We have the following by the scaling property of the Brownian local time; for each c > 0,

$$\{\ell(t,x); t \ge 0, x \ge 0\} \stackrel{d}{=} \Big\{\frac{1}{\sqrt{c}}\ell(ct,\sqrt{c}x); t \ge 0, x \ge 0\Big\}.$$

Therefore,

$$\frac{1}{\lambda} \log\{S_{\lambda}(e^{2\lambda t})\} = \frac{1}{\lambda} \log\left\{\int_{[0,\infty)} \ell(e^{2\lambda t}, x) d\widetilde{m}_{\lambda}(x)\right\}$$

$$\frac{d}{dt} = \frac{1}{\lambda} \log\left\{\int_{[0,\infty)} e^{\lambda t} \ell(1, e^{-\lambda t}x) d\widetilde{m}_{\lambda}(x)\right\}$$

$$= t + \frac{1}{\lambda} \log\left\{\int_{[0,\infty)} \ell(1, x) d\widetilde{m}_{\lambda}(e^{\lambda t}x)\right\}.$$
(15)

First, note that

the right-hand side (RHS) of (15) 
$$\leq t + \frac{1}{\lambda} \log\{a \cdot \widetilde{m}_{\lambda}(e^{\lambda t}M)\}, a.s.,$$

where  $M = \sup_{0 \le u \le 1} B(u)$  and  $a = \sup_{x \in [0,\infty)} \ell(1,x)$ . Since t is chosen from the continuity points of  $\xi$ , it is a continuity point of c and hence, we have by (11) that

$$\frac{1}{\lambda}\log \widetilde{m}_{\lambda}(e^{\lambda t}) \to c(t), \quad as \ \lambda \to \infty.$$

Then we can deduce that

$$\limsup_{\lambda \to \infty} RHS \text{ of } (15) \le t + c(t) = \xi(t).$$

Secondly, note that, almost surely,  $\ell(1,0) > 0$  and  $x \mapsto \ell(1,x)$  is continuous. Hence, almost surely, there exists  $\alpha > 0$  such that

$$b := \inf_{0 \le x \le \alpha} \ell(1, x) > \frac{1}{2}\ell(1, 0) > 0.$$

From this, we have

RHS of (15) 
$$\geq t + \frac{1}{\lambda} \log\{b \cdot \widetilde{m}_{\lambda}(e^{\lambda t} \cdot \alpha)\}, \quad a.s.,$$

and hence, we can deduce that

$$\liminf_{\lambda \to \infty} RHS \text{ of } (15) \ge \xi(t), \quad a.s. \quad \Box$$

From now on, we are particularly interested in the case when  $s_{\lambda} \in \Phi$  and  $m_{\lambda} \in \Phi$  are given such that  $s_{\lambda} \in \Phi_{\infty}$  and  $x \mapsto s_{\lambda}(x)$  is strictly increasing and continuous. And  $\widetilde{m}_{\lambda}$  is defined by

$$\widetilde{m}_{\lambda} = m_{\lambda} \circ s_{\lambda}^{-1}, \quad \text{i.e.}, \quad \widetilde{m}_{\lambda}(x) = m_{\lambda}(s_{\lambda}^{-1}(x)).$$
 (16)

In such a case, we have the Feller generator  $\mathcal{L}_{\lambda} = \frac{d}{dm_{\lambda}} \frac{d}{ds_{\lambda}}$  on  $[0, \infty)$  and the reflecting diffusion process  $X_{\lambda} = (X_{\lambda}(t), P_x)$  on  $[0, \infty)$  is uniquely associated with  $\mathcal{L}_{\lambda}$ . Note that  $X_{\lambda}$  under  $P_0$  is given from  $BM^0(\mathbb{R}) B = (B(t))$  by

$$X_{\lambda}(t) = s_{\lambda}^{-1}(B(S_{\lambda}^{-1}(t))), \quad t \ge 0.$$

We assume that, for some  $a = (a(x)) \in \Phi_{\infty}$  and  $b = (b(x)) \in \Phi$ ,

(A.1)  $e_{\lambda}^{-1} \circ s_{\lambda} \longrightarrow a \text{ in } \Phi \text{ as } \lambda \longrightarrow \infty,$ 

(A.2)  $e_{\lambda}^{-1} \circ m_{\lambda} \longrightarrow b$  in  $\Phi$  as  $\lambda \to \infty$ .

Noting (6) and the relation  $e_{\lambda}^{-1} \circ \widetilde{m}_{\lambda} \circ e_{\lambda} = (e_{\lambda}^{-1} \circ m_{\lambda}) \circ (e_{\lambda}^{-1} \circ s_{\lambda})^{-1}$ , we can deduce the following

**Lemma 4** Under the assumptions (A.1) and (A.2), (11) holds with  $c = b \circ a^{-1}$  if the following condition

$$b(a^{-1}(x-)-) = b(a^{-1}(x))$$
(17)

holds at every continuity point x of  $b \circ a^{-1}$ . In particular, (11) holds if the following assumption (A.3) is satisfied:

(A.3) The set 
$$\{x \in [0,\infty) \mid b(a^{-1}(x-)-) = b(a^{-1}(x))\}$$
 is dense in  $[0,\infty)$ .

The following theorem immediately follows from Lemmas 3 and 4.

**Theorem 5** Let  $s_{\lambda} \in \Phi$  and  $m_{\lambda} \in \Phi$  be given as above. Under the assumptions (A.1), (A.2) and (A.3), it holds that

$$e_{\lambda}^{-1} \circ S_{\lambda} \circ e_{2\lambda} \xrightarrow{p} \xi \quad in \ \Phi \quad as \ \lambda \to \infty,$$
 (18)

where

$$\xi(t) = t + b(a^{-1}(t)), \quad t \ge 0.$$
(19)

**Example 6** Let s(x) = x and  $m(x) = cx^{\frac{1}{\alpha}-1}$  where c > 0 and  $0 < \alpha < 1$ . Set  $s_{\lambda}(x) = s \circ e_{\lambda}$  and  $m_{\lambda} = m \circ e_{\lambda}$ ,  $\lambda > 0$ . Then (A.1) and (A.2) hold with a(x) = x and  $b(x) = (\frac{1}{\alpha} - 1)x$ . Then (A.3) obviously holds and hence, by Theorem 5, we have  $e_{\lambda}^{-1} \circ S_{\lambda} \circ e_{2\lambda} \xrightarrow{p} \xi$  in  $\Phi$  as  $\lambda \to \infty$ . Note that  $\widetilde{m}_{\lambda} = m \circ s^{-1} = m$  and  $\xi(x) = x + b(a^{-1}(x)) = \frac{x}{\alpha}$  so that this implies that

$$\frac{1}{\lambda} \log \Big( \int_{0}^{e^{2\lambda t}} (B(s) \vee 0)^{\frac{1}{\alpha} - 2} ds \Big) \xrightarrow{p} \frac{t}{\alpha} \quad as \ \lambda \to \infty.$$

**Example 7** Let  $w : [0, \infty) \to \mathbb{R}$  be a càdlàg function such that w(0) = 0,  $\limsup_{u\to\infty} w(u) = \infty$  and  $\int_0^\infty e^{\lambda w(u)} du = \infty$  for every  $\lambda > 0$ . Set

$$s_{\lambda}(x) = \int_{0}^{x} e^{\lambda w(u)} du \quad and \quad m_{\lambda}(x) = 2 \int_{0}^{x} e^{-\lambda w(u)} du.$$
(20)

Then (A.1) and (A.2) hold with

$$a(x) = \overline{w}(x) := \sup_{0 \le u \le x} w(u) \quad and \quad b(x) = \underline{w}(x) := \sup_{0 \le u \le x} (-w(u)).$$
(21)

This fact will be proved under a more general situation in Example 8 below. Then  $c(x) = b(a^{-1}(x)) = \underline{w}(\overline{w}^{-1}(x))$  and hence (A.3) in this case means that the set

$$\{x \in [0,\infty) | \underline{w}(\overline{w}^{-1}(x-)-) = \underline{w}(\overline{w}^{-1}(x))\}$$
(22)

is dense in  $[0, \infty)$ . Hence, by Theorem 5, the convergence of  $\Phi$ -valued random variables

$$\frac{1}{\lambda}\log S_{\lambda}(e^{2\lambda t}) \xrightarrow{p} \xi(t) = t + \underline{w}(\overline{w}^{-1}(t)) \quad as \ \lambda \to \infty$$
(23)

can be concluded if the set defined by (22) is dense in  $[0, \infty)$ .

**Example 8** This is a slight generalization of Example 7: This result will be used in Subsection 4.2 through Example 14 of Section 3. Suppose we are given two families of càdlàg functions  $w_{\lambda} : [0, \infty) \to \mathbb{R}$  and  $v_{\lambda} : [0, \infty) \to \mathbb{R}$  for  $\lambda > 0$ , each satisfying the following conditions; denoting by  $f_{\lambda}$  either  $w_{\lambda}$  or  $v_{\lambda}, f_{\lambda}(0) = 0$ ,  $\limsup_{x\to\infty} f_{\lambda}(x) = \infty$  and  $\int_{0}^{\infty} e^{\lambda f_{\lambda}(u)} du = \infty$ . Suppose also  $\phi_{\lambda} \in \Phi, \lambda > 0$ , is given and assume  $\phi_{\lambda}(x) \to x$  for every  $x \in [0, \infty)$  as  $\lambda \to \infty$ . Assume further that a càdlàg function  $w : [0, \infty) \to \mathbb{R}$  is given such that w(0) = 0,  $\limsup_{x \to \infty} w(x) = \infty$  and the following holds:

$$w_{\lambda} \to w \quad in J_1 \quad and \quad v_{\lambda} \to w \quad in J_1 \quad as \lambda \to \infty,$$
(24)

where  $J_1$  is the Skorohod topology (cf. [12]) on the space of càdlàg functions. Under these assumptions,  $s_{\lambda}$  and  $m_{\lambda}$  are defined by

$$s_{\lambda}(x) = \int_{0}^{x} e^{\lambda w_{\lambda}(u)} du \quad and \quad m_{\lambda}(x) = \int_{0}^{\phi_{\lambda}(x)} \{e^{-\lambda w_{\lambda}(u)} + e^{-\lambda v_{\lambda}(u)}\} du.$$
(25)

Then, if a(x) and b(x) are defined by (21) using this limit function w, the same conclusions as Example 7 hold: For example, the proof of " $e_{\lambda}^{-1} \circ s_{\lambda} \to \overline{w}$  in  $\Phi$  as  $\lambda \to \infty$ " is as follows: Let x > 0 be such that  $\overline{w}(x) = \overline{w}(x-)$ . Since  $w_{\lambda} \to w$  in  $J_1$ -metric, it is easy to see that, for any  $\epsilon > 0$ , there exist  $0 < x_1 < x_2 < x$  and  $\lambda_0 > 0$  such that  $w_{\lambda}(u) \ge \overline{w}(x) - \epsilon$  for all  $u \in [x_1, x_2]$  and  $\lambda > \lambda_0$ . Then

$$\liminf_{\lambda \to \infty} \frac{1}{\lambda} \log \left( \int_{0}^{x} e^{\lambda w_{\lambda}(u)} du \right)$$
  
$$\geq \liminf_{\lambda \to \infty} \frac{1}{\lambda} \log \left( (x_{2} - x_{1}) e^{\lambda(\overline{w}(x) - \epsilon)} \right) = \overline{w}(x) - \epsilon.$$

On the other hand,  $w_{\lambda} \to w$  in  $J_1$  implies  $\overline{w}_{\lambda} \to \overline{w}$  in  $J_1$  and hence,

$$\limsup_{\lambda \to \infty} \frac{1}{\lambda} \log \Big( \int_{0}^{x} e^{\lambda w_{\lambda}(u)} du \Big) \le \limsup_{\lambda \to \infty} \frac{1}{\lambda} \log \left( x e^{\lambda \overline{w}_{\lambda}(x)} \right) = \overline{w}(x).$$

The proof of " $e_{\lambda}^{-1} \circ m_{\lambda} \to \underline{w}$  in  $\Phi$  as  $\lambda \to \infty$ " is similar.

**Remark 9** The same conclusion obviously holds if  $s_{\lambda}$  and  $m_{\lambda}$  are modified as

$$s_{\lambda}(x) = \int_{0}^{x} e^{\lambda w(u)} du \cdot \rho_{1}(\lambda) \quad and$$
$$m_{\lambda}(x) = \int_{0}^{\phi_{\lambda}(x)} \{e^{-\lambda w_{\lambda}(u)} + e^{-\lambda v_{\lambda}(u)}\} du \cdot \rho_{2}(\lambda)$$

where  $\rho_i(\lambda) > 0$  and  $\frac{1}{\lambda} \log \rho_i(\lambda) \to 0$  as  $\lambda \to \infty$ , i = 1, 2. A typical example is the case when  $\rho_i(\lambda) = \alpha_i \lambda^{\beta_i}$  with  $\alpha_i > 0$  and  $\beta_i \ge 0$ , i = 1, 2.

# 3 Asymptotics of occupation times on the positive side of a class of diffusions on $\mathbb{R}$ .

Suppose we are given, for each  $\lambda > 0$ , a strictly increasing and continuous function  $s_{\lambda} : \mathbb{R} \to \mathbb{R}$  and a positive Radon measure  $m_{\lambda}(dx)$  on  $\mathbb{R}$ . We assume that  $\lim_{x\to-\infty} s_{\lambda}(x) = -\infty$  and  $\lim_{x\to\infty} s_{\lambda}(x) = \infty$  for each  $\lambda > 0$ . Then the unique recurrent (generalized) diffusion  $\mathbf{X}_{\lambda} = (X_{\lambda}(t), P_x)$  on  $\mathbb{R}$  is associated with the Feller generator  $\mathcal{L}_{\lambda} = \frac{d}{dm_{\lambda}} \frac{d}{ds_{\lambda}}$ : Strictly speaking, the state space of  $\mathbf{X}_{\lambda}$  is the support  $E_{\lambda}$  of the measure  $m_{\lambda}$ . We are interested in the long time asymptotic behavior of the occupation time

$$A_{\lambda}(t) = \int_{0}^{t} \mathbb{1}_{[0,\infty)}(X_{\lambda}(s)) \, ds, \quad t \ge 0.$$
(26)

In order to apply the results in Section 2, we define  $s_{\pm}^{\lambda}$  and  $m_{\pm}^{\lambda}$  as elements in  $\Phi$  as follows:

$$s^{\lambda}_{+}(x) = s_{\lambda}(x) - s_{\lambda}(0), \quad s^{\lambda}_{-}(x) = s_{\lambda}(0) - s_{\lambda}(-x), \quad x \ge 0$$
 (27)

and

$$m_{+}^{\lambda}(x) = m_{\lambda}([0, x]), \quad m_{-}^{\lambda}(x) = m_{\lambda}([-x, 0]), \quad x \ge 0.$$
 (28)

Define

$$\widetilde{m}_{+}^{\lambda} = m_{+}^{\lambda} \circ (s_{+}^{\lambda})^{-1} \quad \text{and} \quad \widetilde{m}_{-}^{\lambda} = m_{-}^{\lambda} \circ (s_{-}^{\lambda})^{-1}.$$
 (29)

For a  $BM^0(\mathbb{R})$  B = (B(t)) with the local time  $\ell(t, x)$ , set

$$S_{\lambda}^{+}(t) = \int_{[0,\infty)} \ell(t,x) \, d\widetilde{m}_{+}^{\lambda}(x), \quad S_{\lambda}^{-}(t) = \int_{[0,\infty)} \ell(t,-x) \, d\widetilde{m}_{-}^{\lambda}(x), \tag{30}$$

and

$$S_{\lambda}(t) = S_{\lambda}^{+}(t) + S_{\lambda}^{-}(t).$$
(31)

We assume that  $(s_{+}^{\lambda}, m_{+}^{\lambda})$  and  $(s_{-}^{\lambda}, m_{-}^{\lambda})$  satisfy the assumptions (A.1), (A.2) and (A.3) of Section 2; namely, for each of + and -,

(A.1)' 
$$e_{\lambda}^{-1} \circ s_{\pm}^{\lambda} \longrightarrow a_{\pm} \text{ in } \Phi \text{ as } \lambda \to \infty, \text{ with } a_{\pm} \in \Phi_{\infty}$$

(A.2)' 
$$e_{\lambda}^{-1} \circ m_{\pm}^{\lambda} \longrightarrow b_{\pm}$$
 in  $\Phi$  as  $\lambda \to \infty$ 

and

(A.3)' the sets 
$$\{x \in [0,\infty) \mid b_+(a_+^{-1}(x-)-) = b_+(a_+^{-1}(x))\}$$
  
and  $\{x \in (0,\infty) \mid b_-(a_-^{-1}(x-)-) = b_-(a_-^{-1}(x))\}$  are dense in  $[0,\infty)$ 

Then, by Theorem 5, we have the following joint convergence:

$$\left(e_{\lambda}^{-1} \circ S_{\lambda}^{+} \circ e_{2\lambda}, e_{\lambda}^{-1} \circ S_{\lambda}^{-} \circ e_{2\lambda}\right) \xrightarrow{p} (\xi_{+}, \xi_{-}) \text{ in } \Phi \times \Phi \text{ as } \lambda \to \infty$$
(32)

where

$$\xi_{+}(t) = t + b_{+}(a_{+}^{-1}(t)) \text{ and } \xi_{-}(t) = t + b_{-}(a_{-}^{-1}(t)).$$
 (33)

By a standard argument using the inequality

$$S_{\lambda}^{+}(t) \vee S_{\lambda}^{-}(t) \leq S_{\lambda}^{+}(t) + S_{\lambda}^{-}(t) \leq 2\left(S_{\lambda}^{+}(t) \vee S_{\lambda}^{-}(t)\right),$$

we deduce from (32) that

$$e_{\lambda}^{-1} \circ S_{\lambda} \circ e_{2\lambda} \xrightarrow{p} \xi_{+} \lor \xi_{-} \text{ in } \Phi \text{ as } \lambda \to \infty$$
 (34)

where  $\xi_+ \lor \xi_- \in \Phi$  is defined by

$$(\xi_+ \vee \xi_-)(t) = \max\{\xi_+(t), \xi_-(t)\}.$$
(35)

Summing up these results, we have obtained the following

**Theorem 10** Assume that  $s_{\lambda}$  and  $m_{\lambda}$  satisfy the assumptions (A.1)', (A.2)' and (A.3)'. Then we have the following joint convergence:

$$\begin{pmatrix} e_{\lambda}^{-1} \circ S_{\lambda}^{+} \circ e_{2\lambda}, \ e_{\lambda}^{-1} \circ S_{\lambda}^{-} \circ e_{2\lambda}, \ e_{\lambda}^{-1} \circ S_{\lambda} \circ e_{2\lambda} \end{pmatrix}$$

$$\xrightarrow{p} \quad (\xi_{+}, \xi_{-}, \xi_{+} \lor \xi_{-}) \quad in \ \Phi \times \Phi \times \Phi \ as \ \lambda \to \infty$$

$$(36)$$

where  $\xi_+$  and  $\xi_-$  are defined by (33).

As in [9], we have

$$A_{\lambda} = S_{\lambda}^{+} \circ S_{\lambda}^{-1}, \quad i.e., A_{\lambda}(t) = S_{\lambda}^{+}(S_{\lambda}^{-1}(t)), \quad t \ge 0.$$

$$(37)$$

By the Skorohod realization theorem, we can realize, on a suitable probability space, a family of  $\Phi$ -valued random variables  $\tilde{S}^+_{\lambda}, \tilde{S}^-_{\lambda}$  such that, for each  $\lambda$ ,  $(S^+_{\lambda}, S^-_{\lambda}) \stackrel{d}{=} (\tilde{S}^+_{\lambda}, \tilde{S}^-_{\lambda})$  and, setting  $\tilde{S}_{\lambda} = \tilde{S}^+_{\lambda} + \tilde{S}^-_{\lambda}$ ,

$$\begin{pmatrix} e_{\lambda}^{-1} \circ \tilde{S}_{\lambda}^{+} \circ e_{2\lambda}, \ e_{\lambda}^{-1} \circ \tilde{S}_{\lambda}^{-} \circ e_{2\lambda}, \ e_{\lambda}^{-1} \circ \tilde{S}_{\lambda} \circ e_{2\lambda} \end{pmatrix}$$
  
  $\longrightarrow \quad (\xi_{+}, \xi_{-}, \xi_{+} \lor \xi_{-}) \quad a.s. \text{ in } \Phi \times \Phi \times \Phi \text{ as } \lambda \to \infty.$  (38)

Hence, if we set  $\tilde{A}_{\lambda}(t) = \tilde{S}_{\lambda}^{+}(\tilde{S}_{\lambda}^{-1}(t))$ , then we have, as  $\Phi$ -valued random variables,

$$A_{\lambda} \stackrel{d}{=} \widetilde{A}_{\lambda} \quad \text{for each} \quad \lambda > 0. \tag{39}$$

Note that

$$\begin{aligned} e_{\lambda}^{-1} \circ \widetilde{S}_{\lambda}^{+} \circ e_{2\lambda} \circ (e_{\lambda}^{-1} \circ \widetilde{S}_{\lambda} \circ e_{2\lambda})^{-1} \\ &= e_{\lambda}^{-1} \circ \widetilde{S}_{\lambda}^{+} \circ (\widetilde{S}_{\lambda})^{-1} \circ e_{\lambda} = e_{\lambda}^{-1} \circ \widetilde{A}_{\lambda} \circ e_{\lambda}. \end{aligned}$$

Also, note that  $(\xi_+ \vee \xi_-)^{-1}(t)$  is continuous in t because  $\xi_+$  and  $\xi_-$ , hence  $\xi_+ \vee \xi_-$ , are strictly increasing. Then, by noting the general fact concerning (6) and (7), we can now deduce from (38) the following: If  $t \in [0, \infty)$  is such that

$$\xi_{+}((\xi_{+} \vee \xi_{-})^{-1}(t)) = \xi_{+}((\xi_{+} \vee \xi_{-})^{-1}(t) - ),$$
(40)

then,

$$(e_{\lambda}^{-1} \circ \tilde{A}_{\lambda} \circ e_{\lambda})(t) \left( = \frac{1}{\lambda} \log \left\{ \tilde{A}_{\lambda} (e^{\lambda t} - 1) + 1 \right\} \right) \longrightarrow \xi_{+} ((\xi_{+} \lor \xi_{-})^{-1}(t)) \text{ as } \lambda \to \infty, a.s.$$
(41)

From this fact, we obtain the following:

**Theorem 11** We assume that  $s_{\lambda}$  and  $m_{\lambda}$  satisfy (A.1)', (A.2)' and (A.3)'. If  $t \in [0, \infty)$  is such that

$$\xi_{+}((\xi_{-})^{-1}(t) - ) = \xi_{+}((\xi_{-})^{-1}(t)), \tag{42}$$

then it holds that

$$\frac{1}{\lambda} \log A_{\lambda}(e^{\lambda t}) \xrightarrow{p} \xi_{+}((\xi_{-})^{-1}(t)) \wedge t, \quad as \ \lambda \to \infty.$$
(43)

**Proof.** It is sufficient to prove in the above realization that, if (42) holds, then,

$$\frac{1}{\lambda}\log\tilde{A}_{\lambda}(e^{\lambda t}) \longrightarrow \xi_{+}((\xi_{-})^{-1}(t)) \wedge t, \quad as \ \lambda \to \infty, \ a.s.$$

$$(44)$$

If  $(\xi_{-})^{-1}(t) \leq (\xi_{+})^{-1}(t)$ , then (40) follows from (42) and hence, (44) follows from (41).

Next, consider the case when

$$(\xi_{-})^{-1}(t) > (\xi_{+})^{-1}(t) \tag{45}$$

holds. Setting, for simplicity,

$$\varphi_{\lambda}^{\pm}(s) = \frac{1}{\lambda} \log \widetilde{S}_{\lambda}^{\pm}(e^{2\lambda s}) \text{ and } \psi_{\lambda}(s) = \frac{1}{\lambda} \log \widetilde{S}_{\lambda}(e^{2\lambda s}),$$

we have

$$(\varphi_{\lambda}^{\pm})^{-1}(s) \to (\xi_{\pm})^{-1}(s) \text{ and } \psi_{\lambda}(s)^{-1} \to (\xi_{\pm})^{-1} \land (\xi_{\pm})^{-1}(s)$$

as  $\lambda \to \infty$  uniformly in *s* on any bounded interval, *a.s.* (Note that  $(\xi_{\pm})^{-1}$  and  $(\xi_{+})^{-1} \wedge (\xi_{-})^{-1}$  are continuous because  $\xi_{+}$  and  $\xi_{-}$  are strictly increasing). Then, for fixed *t* satisfying (42) and (45), we have, from the inequality

$$\widetilde{S}_{\lambda}(s) = \widetilde{S}_{\lambda}^{+}(s) + \widetilde{S}_{\lambda}^{-}(s) \le 2(\widetilde{S}_{\lambda}^{+}(s) \lor \widetilde{S}_{\lambda}^{-}(s)),$$

that, for some  $\lambda_0$  large enough,

$$\psi_{\lambda}^{-1}(t) \ge (\varphi_{\lambda}^{+})^{-1} \left( t - \frac{\log 2}{\lambda} \right) \wedge (\varphi_{\lambda}^{-})^{-1} \left( t - \frac{\log 2}{\lambda} \right) = (\varphi_{\lambda}^{+})^{-1} \left( t - \frac{\log 2}{\lambda} \right),$$

for all  $\lambda > \lambda_0$ . Hence

$$\varphi_{\lambda}^{+}(\psi_{\lambda}^{-1}(t)) \ge \varphi_{\lambda}^{+}\left((\varphi_{\lambda}^{+})^{-1}\left(t - \frac{\log 2}{\lambda}\right)\right) \longrightarrow t, \quad as \ \lambda \to \infty$$

and therefore,

$$\liminf_{\lambda \to \infty} \frac{1}{\lambda} \log \widetilde{A}_{\lambda}(e^{\lambda t}) = \liminf_{\lambda \to \infty} \varphi_{\lambda}^{+}(\psi_{\lambda}^{-1}(t)) \ge t, \ a.s..$$

On the other hand, we have obviously,

$$\limsup_{\lambda \to \infty} \frac{1}{\lambda} \log \widetilde{A}_{\lambda}(e^{\lambda t}) \le t, \ a.s.,$$

so that

$$\lim_{\lambda \to \infty} \frac{1}{\lambda} \log \widetilde{A}_{\lambda}(e^{\lambda t}) = t = \xi_+((\xi_-)^{-1}(t)) \wedge t, \ a.s.$$

in this case as well.  $\Box$ 

**Example 12** This example corresponds to Example 6 of Section 2. We consider the  $\mathcal{L} = \frac{d}{dm} \frac{d}{ds}$ -diffusion process  $X = (X(t), P_x)$  on  $\mathbb{R}$  where  $s(x) = x, x \in \mathbb{R}$ , and

$$m(x) = \begin{cases} c_+ x^{\frac{1}{\alpha} - 1}, & x \ge 0, \\ -c_- (-x)^{\frac{1}{\beta} - 1}, & x < 0, \end{cases}$$

for some  $c_+ > 0, c_- > 0$  and  $0 < \alpha < 1, 0 < \beta < 1$ . Let  $s^+(x) = s^-(x) = x$  for  $x \ge 0$  and  $m^+(x) = c_+ x^{\frac{1}{\alpha}-1}, m^-(x) = c_- x^{\frac{1}{\beta}-1}, x \ge 0$ . Set  $s_{\lambda}^{\pm} = s^{\pm} \circ e_{\lambda}$  and  $m_{\lambda}^{\pm} = m^{\pm} \circ e_{\lambda}$ . From Example 6, we have  $\xi_+(x) = \frac{x}{\alpha}$  and  $\xi_-(x) = \frac{x}{\beta}$  so that

$$\xi_+((\xi_-)^{-1}(t)) = \frac{\beta}{\alpha}t, \quad t \ge 0.$$

Hence

$$\xi_+((\xi_-)^{-1}(t)) \wedge t = \begin{cases} \frac{\beta}{\alpha}t, & \beta < \alpha, \\ t, & \alpha \le \beta. \end{cases}$$

In this case, the scale  $s_{\lambda}$  on  $\mathbb{R}$  is determined by  $s_{\lambda}(x) = s_{\lambda}^{+}(x), x \geq 0$  and  $s_{\lambda}(x) = -s_{\lambda}^{-}(-x), x < 0$ . Similarly the speed measure  $dm_{\lambda}$  on  $\mathbb{R}$  is determined by  $m_{\lambda}([0, x]) = m_{\lambda}^{+}(x), x \geq 0$  and  $m_{\lambda}([x, 0]) = m_{\lambda}^{-}(-x), x < 0$ . Then, if  $X_{\lambda} = (X_{\lambda}(t), P_{x}^{\lambda})$  is the  $\mathcal{L}_{\lambda} = \frac{d}{dm_{\lambda}} \frac{d}{ds_{\lambda}}$ -diffusion, we have

$$\{X_{\lambda}(t)\} \stackrel{d}{=} \{s_{\lambda}^{-1}(X(t))\}$$

and hence  $\{A_{\lambda}(t)\} \stackrel{d}{=} \{A(t)\}$ . Thus, from Theorem 3.2, we can deduce that, as  $\lambda \to \infty$ ,

$$\frac{1}{\lambda} \log A(e^{\lambda t}) \longrightarrow \begin{cases} \frac{\beta}{\alpha} t, & \beta < \alpha, \\ t, & \alpha \le \beta, \end{cases}$$
(46)

in the sense of  $\Phi$ -valued random variables and also, in the sense of finite dimensional distributions. In particular, we have

$$\frac{\log A(t)}{\log t} \longrightarrow \begin{cases} \frac{\beta}{\alpha}, & \beta < \alpha, \\ 1, & \alpha \le \beta. \end{cases}$$
(47)

This is an improvement of the law convergence

$$\frac{A(t)}{t} \xrightarrow{p} \begin{cases} 0, & \beta < \alpha, \\ 1, & \alpha \le \beta, \end{cases} \quad as \ t \to \infty.$$

**Example 13** This example corresponds to Example 7 of Section 2. Let w:  $\mathbb{R} \ni t \mapsto w(t) \in \mathbb{R}$  be a càdlàg function such that

 $w(0)=w(0-)=0,\quad \limsup_{u\to\infty}w(u)=\limsup_{u\to-\infty}w(u)=\infty,$ 

$$\liminf_{u\to\infty} w(u) = \liminf_{u\to-\infty} w(u) = -\infty$$

and

$$\int_{0}^{\infty} e^{\lambda w(u)} du = \int_{-\infty}^{0} e^{\lambda w(u)} du = \infty \quad for \ every \quad \lambda > 0.$$

Set

$$s_{\lambda}(x) = \int_{0}^{x} e^{\lambda w(u)} du, \quad -\infty < x < \infty$$
(48)

and

$$m_{\lambda}(x) = 2 \int_{0}^{x} e^{-\lambda w(u)} du, \quad -\infty < x < \infty,$$
(49)

so that  $m_{\lambda}(dx) = dm_{\lambda}(x) = 2e^{-\lambda w(x)}dx$ .  $X_{\lambda} = (X_{\lambda}(t), P_x)$  is the recurrent diffusion process on  $\mathbb{R}$  associated with the Feller generator  $\mathcal{L}_{\lambda} = \frac{d}{dm_{\lambda}}\frac{d}{ds_{\lambda}}$ . Let  $A_{\lambda}(t) = \int_0^t \mathbb{1}_{[0,\infty)}(X_{\lambda}(s)) ds$ ,  $\lambda > 0$ . In order to apply the results in Example 7, we define  $s_{\pm}^{\lambda}, m_{\pm}^{\lambda}, \overline{w_{\pm}}$ , and  $\underline{w_{\pm}}$  as elements in  $\Phi$ ;

$$s_{+}^{\lambda}(x) = \int_{0}^{x} e^{\lambda w(u)} du, \ s_{-}^{\lambda}(x) = \int_{-x}^{0} e^{\lambda w(u)} du, \quad x \ge 0,$$
(50)

$$m_{+}^{\lambda}(x) = 2 \int_{0}^{x} e^{-\lambda w(u)} du, \ m_{-}^{\lambda}(x) = 2 \int_{-x}^{0} e^{-\lambda w(u)} du, \quad x \ge 0.$$
(51)

We define  $w_{\pm}: [0, \infty) \to \mathbb{R}$  by

$$w_{+}(x) = w(x)$$
 and  $w_{-}(x) = w(-x - 0).$  (52)

Then  $\overline{w_{\pm}}$  and  $\underline{w_{\pm}}$  are defined by (21); namely, for each of + and -,

$$\overline{w_{\pm}}(x) = \sup_{0 \le u \le x} w_{\pm}(u) \quad and \quad \underline{w_{\pm}}(x) = \sup_{0 \le u \le x} (-w_{\pm}(u)).$$
(53)

Then (A.1)' and (A.2)' hold with  $a_{\pm}$  and  $b_{\pm}$  defined by (21) through  $w_{\pm}$ , respectively. (A.3)' holds if the following holds:

The sets 
$$\left\{ x \in [0,\infty) \mid \underline{w_+}((\overline{w_+})^{-1}(x_-)) = \underline{w_+}((\overline{w_+})^{-1}(x)) \right\}$$
  
and  $\left\{ x \in [0,\infty) \mid \underline{w_-}((\overline{w_-})^{-1}(x_-)) = \underline{w_-}((\overline{w_-})^{-1}(x)) \right\}$   
are both dense in  $[0,\infty)$ . (54)

Hence, by Theorem 10, we have the following conclusion: Assume that (54) holds. Let  $\xi_{\pm} \in \Phi_{\infty}$  be defined by

$$\xi_{+}(t) = t + \underline{w_{+}} \circ \overline{w_{+}}^{-1}(t) \text{ and } \xi_{-}(t) = t + \underline{w_{-}} \circ \overline{w_{-}}^{-1}(t), \ t \ge 0.$$
(55)

If t is such that

$$\xi_{+}((\xi_{-})^{-1}(t) - ) = \xi_{+}((\xi_{-})^{-1}(t)),$$
(56)

then it holds that

$$\frac{1}{\lambda} \log A_{\lambda}(e^{\lambda t}) \xrightarrow{p} \xi_{+}((\xi_{-})^{-1}(t)) \wedge t, \quad \lambda \to \infty.$$
(57)

**Example 14** This is a modification of Example 13, which corresponds to that in Example 8 of Section 2. Suppose we are given, for each of + and -, and for  $\lambda > 0$ , families  $w_{\lambda}^{\pm}, v_{\lambda}^{\pm}, w^{\pm}$  and  $\phi_{\lambda}^{\lambda}$  satisfying the same conditions as  $w_{\lambda}, v_{\lambda}, w$  and  $\phi_{\lambda}$  in Example 8. Then, we have  $s_{\lambda}^{\pm}$  and  $m_{\lambda}^{\pm}$ , respectively, in the same way as (25) in Example 8. Now, these can be extended to  $s_{\lambda}$  and  $m_{\lambda}$  on  $\mathbb{R}$  by setting  $s_{\lambda}(x) = s_{\lambda}^{+}(x), x \geq 0$  and  $s_{\lambda}(x) = -s_{\lambda}^{-}(-x), x < 0$ , and  $m_{\lambda}(x) = m_{\lambda}^{+}(x), x \geq 0$  and  $m_{\lambda}(x) = -m_{\lambda}^{-}(-x-0), x < 0$ . Hence we have the Feller generator  $\mathcal{L}_{\lambda} = \frac{d}{dm_{\lambda}} \frac{d}{ds_{\lambda}}$  on  $\mathbb{R}$  and the associated recurrent (generalized) diffusion  $X_{\lambda} = (X_{\lambda}(t), P_{x})$  on the support of  $dm_{\lambda}$ . Then, for the occupation time  $A_{\lambda}(t) = \int_{0}^{t} 1_{[0,\infty)}(X_{\lambda}(u)) du$ , we have the same conclusion as in Example 13; in particular, the limit process can be described in terms of the limit function  $w^{\pm}$  on  $[0, \infty)$ .

**Remark 15** In Examples 13 and 14, we have obviously the same conclusion if  $s_{\lambda}^{\pm}$  and  $m_{\lambda}^{\pm}$  are replaced, respectively, by those multiplied by some  $\rho(\lambda) > 0$ such that  $\lim_{\lambda\to\infty}\frac{1}{\lambda}\log\rho(\lambda) = 0$ . A typical example is the case  $\rho(\lambda) = c_1\lambda^{c_2}$ with positive constants  $c_1$  and  $c_2$ .

# 4 Long time asymptotics of occupation times for diffusions and random walks in random environments

We would apply the results of Section 3 to the study of the long time asymptotic behaviors of occupation times on the positive side for diffusions on  $\mathbb{R}$  and random walks on  $\mathbb{Z}$  in random environments.

# 4.1. The case of Brox model and its generalization to stable environments.

Let  $w : [0, \infty) \to \mathbb{R}$  be a càdlàg function such that w(0) = 0,  $\limsup_{u \to \infty} w(u) = \infty$  and  $\int_0^\infty e^{\lambda w(u)} du = \infty$  for every  $\lambda > 0$ . We denote the totality of such functions by  $W_+$ , which is a Lusin space under the Skorohod topology. For a pair  $w = (w_+, w_-) \in W_+ \times W_+ =: W$ , define  $s_{\pm}^w \in \Phi_{\infty}$  and  $m_{\pm}^w \in \Phi$ , for each of + and -, by

$$s_{\pm}^{w}(x) = \int_{0}^{x} e^{w_{\pm}(u)} du \quad \text{and} \quad m_{\pm}^{w}(x) = 2 \int_{0}^{x} e^{-w_{\pm}(u)} du.$$
 (58)

These  $s^w_{\pm}$  and  $m^w_{\pm}$  determine the scale  $s^w$  and the speed measure  $dm^w$  on  $\mathbb{R}$ ;

$$s^{w}(x) = 1_{\{x \ge 0\}} s^{w}_{+}(x) - 1_{\{x < 0\}} s^{w}_{-}(-x)$$
(59)

and

$$dm^{w}(x) = 2\left\{1_{\{x \ge 0\}}e^{-w_{+}(x)} dx + 1_{\{x < 0\}}e^{-w_{-}(-x)} dx\right\}.$$
(60)

Then we have the Feller generator  $\mathcal{L}^w = \frac{d}{dm^w} \frac{d}{ds^w}$  and the unique recurrent diffusion  $X^w = (X^w(t), P^w_x)$  on  $\mathbb{R}$  associated with  $\mathcal{L}^w$ . We suppose that  $X^w$  is realized on the space  $\Omega$  of all continuous functions  $\omega : [0, \infty) \to \mathbb{R}$  as  $X^w(t) = \omega(t)$  so that  $P^w_x$  is the Borel probability on  $\Omega$  concentrated on  $\{\omega \mid \omega(0) = x\}$ .

Let  $0 < \alpha_+ \leq 2$  and  $0 < \alpha_- \leq 2$ . Let  $(X_+(t), X_-(t))$  be a pair of mutually independent one-dimensional symmetric stable processes  $X_+(t)$  and  $X_-(t)$  of index  $\alpha_+$  and  $\alpha_-$ , respectively, with  $X_+(0) = X_-(0) = 0$ , so that

$$E[e^{i(\xi_+X_+(t)+\xi_-X_-(t))}] = e^{-(c_+|\xi_+|^{\alpha_+}+c_-|\xi_-|^{\alpha_-})t}, \quad \xi_+, \xi_- \in \mathbb{R}$$

for some positive constants  $c_+$  and  $c_-$ . The values  $c_+$  and  $c_-$  are irrelevant in future discussions. It is well-known that  $\limsup_{t\to\infty} X_{\pm}(t) = \infty$  and  $\int_0^{\infty} e^{\lambda X_{\pm}(t)} dt = \infty$  for every  $\lambda > 0$  almost surely, so that  $(X_+(t), X_-(t))$ is a  $W = W_+ \times W_+$ -valued random variable. We denote its law on W by  $P_{\alpha_+,\alpha_-}(dw)$ . Then we have a stochastic process  $\overline{X} = (\overline{X}(t), \overline{P}_x)$  realized on  $\Omega \times W$  where  $\overline{X}(t) = \omega(t), \omega \in \Omega$ , and  $\overline{P}_x(d\omega, dw) = P_x^w(d\omega) \cdot P_{\alpha_+,\alpha_-}(dw)$ . This model has been introduced by Y. Suzuki ([14]): Indeed, she introduced a more general model in which  $P_{\alpha_+,\alpha_-}$  is the law of the pair of mutually independent self-similar processes on  $\mathbb{R}$  with index  $\alpha_+ > 0$  and  $\alpha_- > 0$ , respectively. We restrict ourselves to the case of the pair of independent symmetric stable processes: As we shall see, this restriction is only needed below in verifying Lemmas 18 and 19, and in obtaining an explicit formula for the limit law in Theorem 23. The case of mutually independent Wiener processes is well-known as the Brox model (cf. [5]).

For  $w = (w_+, w_-) \in W (= W_+ \times W_+)$  and  $\lambda > 0$ , we introduce, for each of + and -,

$$s_{\pm}^{\lambda,w}(x) = \lambda^{\alpha_{\pm}} \int_{0}^{x} e^{\lambda w_{\pm}(u)} du, \quad x \ge 0$$

and

$$m_{\pm}^{\lambda,w}(x) = 2\lambda^{\alpha_{\pm}} \int_{0}^{x} e^{-\lambda w_{\pm}(u)} du, \quad x \ge 0.$$

These  $s_{\pm}^{\lambda,w}$  and  $m_{\pm}^{\lambda,w}$  determine the scale  $s_{\lambda}^{w}$  and the speed measure  $dm_{\lambda}^{w}$  on  $\mathbb{R}$  in the same way as (59) and (60) above. Then, we have the unique  $\mathcal{L}^{\lambda,w} = \frac{d}{dm_{\lambda}^{w}} \frac{d}{ds_{\lambda}^{w}}$ diffusion process  $X^{\lambda,w} = (X(t), P_{x}^{\lambda,w})$  on  $\mathbb{R}$  which we realize on  $\Omega$  as  $X(t) = \omega(t), \omega \in \Omega$ . Also we have the stochastic process  $\overline{X}^{\lambda} = (\overline{X}^{\lambda}(t), \overline{P}_{x}^{\lambda})$  realized on  $\Omega \times W$  where  $\overline{X}^{\lambda}(t) = \omega(t), \omega \in \Omega$ , and  $\overline{P}_{x}^{\lambda}(d\omega, dw) = P_{x}^{\lambda,w}(d\omega) P_{\alpha_{+},\alpha_{-}}(dw)$ .

Let, for a > 0 and b > 0,  $T_{a,b} : \mathbb{R} \to \mathbb{R}$  be a homeomorphism on  $\mathbb{R}$  defined by

$$T_{a,b}(x) = a \cdot 1_{\{x \ge 0\}} \cdot x + b \cdot 1_{\{x < 0\}} \cdot x$$

**Lemma 16** For each  $\lambda > 0$ ,

$$\left(T_{\lambda^{-\alpha_{+}},\lambda^{-\alpha_{-}}}(\overline{X}),\overline{P}_{0}\right) \stackrel{d}{=} \left(\overline{X}^{\lambda},\overline{P}_{0}^{\lambda}\right).$$
 (61)

**Proof.** Generally, if  $Y = (Y(t), P_x)$  is  $\mathcal{L} = \frac{d}{dm} \frac{d}{ds}$ -Feller diffusion on  $\mathbb{R}$  and  $T : \mathbb{R} \to \mathbb{R}$  is a homeomorphism of  $\mathbb{R}$ , then  $T(Y) = (T(Y(t)), P_x)$  is  $\tilde{\mathcal{L}} = \frac{d}{d\tilde{m}} \frac{d}{d\tilde{s}}$ -Feller diffusion on  $\mathbb{R}$  with  $d\tilde{m} = d(m \circ T^{-1})$  and  $\tilde{s} = s \circ T^{-1}$ . Using this fact and the self-similarity of stable processes:

$$\left\{\left(w_{+}(\lambda^{\alpha_{+}}t), w_{-}(\lambda^{\alpha_{-}}t), P_{\alpha_{+},\alpha_{-}}\right)\right\} \stackrel{d}{=} \left\{\left(\lambda w_{+}(t), \lambda w_{-}(t), P_{\alpha_{+},\alpha_{-}}\right)\right\},$$

(61) is easily concluded.  $\Box$ 

## Corollary 17 If

 $\begin{aligned} A(t) &= \int_0^t \mathbf{1}_{[0,\infty)}(\overline{X}(u)) du \text{ and } A_{\lambda}(t) = \int_0^t \mathbf{1}_{[0,\infty)}(\overline{X}_{\lambda}(u)) du, \text{ then, for each } \lambda > \\ 0, \text{ we have} \\ \left( \{A(t)\}_{t \ge 0}, \overline{P}_0 \right) \stackrel{d}{=} \left( \{A_{\lambda}(t)\}_{t \ge 0}, \overline{P}_0^{\lambda} \right). \end{aligned}$ 

The limiting property of  $A_{\lambda}(e^{\lambda t})$  under  $\overline{P}_{0}^{\lambda}$  as  $\lambda \to \infty$  can be studied by results in Example 13 and Remark 15. For  $w = (w_{+}, w_{-}) \in W_{+} \times W_{+}(=W)$ , we define  $\xi_+(t)$  and  $\xi_-(t)$  by (55). Note that these may be regarded as stochastic processes under  $\overline{P}_0$  as well as under  $\overline{P}_0^{\lambda}$  on  $\Omega \times W$ .

**Lemma 18** Under  $P_{\alpha_+,\alpha_-}$  (and hence, under  $\overline{P}_0^{\lambda}$ ), (54) holds almost surely.

**Proof.** Note first that  $w_+ : [0, \infty) \ni x \mapsto w_+(x) \in \mathbb{R}$  and  $w_- : [0, \infty) \ni x \mapsto w_-(x) \in \mathbb{R}$  are mutually independent stable processes under  $P_{\alpha_+,\alpha_-}$ . Then, by known properties of stable processes, we can easily see that, for each fixed  $x \ge 0$ , it holds  $a.s.(P_{\alpha_+,\alpha_-})$  that

$$\underline{w_{+}}((\overline{w_{+}})^{-1}(x-) - ) = \underline{w_{+}}((\overline{w_{+}})^{-1}(x))$$

and

$$\underline{w_{-}}((\overline{w_{-}})^{-1}(x-)) = \underline{w_{-}}((\overline{w_{-}})^{-1}(x)).$$

By a standard *Fubini argument*, we deduce that these identities hold for almost all  $x \in [0, \infty)$ ,  $P_{\alpha_+,\alpha_-}$ -almost surely. Thus (54) holds for  $a.a.w (P_{\alpha_+,\alpha_-})$ .  $\Box$ 

**Lemma 19** For each  $t \ge 0$ , (56) holds almost surely under  $P_{\alpha_+,\alpha_-}$  (and hence, under  $\overline{P}_0^{\lambda}$ ).

**Proof.** This is easily provided by the independence of  $\xi_+$  and  $\xi_-$  combined with the fact that  $\xi_+$  and  $\xi_-$  have no time of fixed discontinuity.  $\Box$ 

Thus by Example 13 and Remark 15, combined with Lemmas 18 and 19, we can conclude that, under  $\overline{P}_{0}^{\lambda}$ ,

$$\left\{\frac{1}{\lambda}\log A_{\lambda}(e^{\lambda t})\right\}_{t\geq 0} \longrightarrow \left\{\xi_{+}((\xi_{-})^{-1}(t))\wedge t\right\}_{t\geq 0}$$

as  $\lambda \to \infty$  in the sense of convergence of all finite-dimensional distributions as well as the convergence in law as  $\Phi$ -valued random variables. Then, by Corollary 17, we immediately obtain the following:

**Theorem 20** Under  $\overline{P}_0$ , we have

$$\left\{\frac{1}{\lambda}\log A(e^{\lambda t})\right\}_{t\geq 0} \longrightarrow \left\{\xi_+((\xi_-)^{-1}(t))\wedge t\right\}_{t\geq 0}, \quad \lambda\to\infty$$

in the sense of convergence of all finite-dimensional distributions as well as the convergence in law as  $\Phi$ -valued random variables. In particular,

$$\frac{1}{\log t} \log A(t) \xrightarrow{d} \xi_+((\xi_-)^{-1}(1)) \wedge 1, \quad as \quad t \to \infty.$$
(62)

From (62), we have, for every  $\beta < 1$ ,

$$\liminf_{t \to \infty} \overline{P}_0 \Big( \frac{1}{\log t} \log A(t) < \beta \Big) \ge \overline{P}_0 \Big( \xi_+ ((\xi_-)^{-1}(1)) < \beta \Big)$$

From this, we can easily deduce that, for every  $\epsilon > 0$ ,

$$\liminf_{t\to\infty} \overline{P}_0\Big(\frac{A(t)}{t} < \epsilon\Big) \ge \overline{P}_0\Big((\xi_-)^{-1}(1) < (\xi_+)^{-1}(1)\Big).$$

By the same argument applied to t - A(t) in place of A(t), we obtain

$$\liminf_{t \to \infty} \overline{P}_0\Big(\frac{A(t)}{t} > 1 - \epsilon\Big) \ge \overline{P}_0\Big((\xi_+)^{-1}(1) < (\xi_-)^{-1}(1)\Big).$$

Since  $\overline{P}_0((\xi_+)^{-1}(1) = (\xi_-)^{-1}(1)) = 0$ , we conclude the following

Corollary 21 Under  $\overline{P}_0$ ,

$$\frac{A(t)}{t} \xrightarrow{d} 1_{\{(\xi_+)^{-1}(1) < (\xi_-)^{-1}(1)\}} \quad as \ t \to \infty.$$

$$(63)$$

Thus, the limit random variable in law of A(t)/t as  $t \to \infty$  is the Bernoulli random variable  $Y_{0,p}$  where

$$p = \overline{P}_0\left((\xi_+)^{-1}(1) < (\xi_-)^{-1}(1)\right) \left(= P_{\alpha_+,\alpha_-}\left((\xi_+)^{-1}(1) < (\xi_-)^{-1}(1)\right)\right).$$
(64)

**Remark 22** As for the almost sure result for the ratio A(t)/t as  $t \to \infty$ , we have the following:  $\overline{P}_0$  -almost surely, (equivalently,  $P_0^w$ -almost surely for  $P_{\alpha_+,\alpha_-}$ -almost all environments  $w = (w_+, w_-)$ ), it holds that

$$\limsup_{t \to \infty} \frac{A(t)}{t} = 1 \quad and \quad \liminf_{t \to \infty} \frac{A(t)}{t} = 0.$$

This fact can be proved by applying a result of Bertoin [1]: Bertoin obtained an integral test for  $s_{\pm}^{w}(x)$  and  $m_{\pm}^{w}(x)$  in order that the above asymptotics for the ratio A(t)/t to hold. We can show that the conditions of the integral test are fulfilled by  $P_{\alpha_{+},\alpha_{-}}$ -almost all  $w = (w_{+}, w_{-})$ : For this, we use the above fact (63) and combine this with the Hewitt-Savage 0-1 law for stable processes  $w_{+}$ and  $w_{-}$ . We omit the details.

The distribution of  $\xi_+((\xi_-)^{-1}(1)) \wedge 1$  can be obtained explicitly as follows.

Theorem 23 It holds that

$$\xi_{+}((\xi_{-})^{-1}(1)) \stackrel{d}{=} \frac{U_{2}}{U_{1}} \tag{65}$$

where  $U_1$  and  $U_2$  are mutually independent (0, 1)-valued random variables such that  $U_1 \stackrel{d}{=} V(\alpha_+)$  and  $U_2 \stackrel{d}{=} V(\alpha_-)$ , where  $V(\alpha)$ ,  $0 < \alpha \leq 2$ , are (0, 1)-valued

random variables with the distribution function  $P(V(\alpha) \leq x) = u_{\alpha}(x), \ 0 < x < 1, \text{ given by}$ 

$$u_{\alpha}(x) = \begin{cases} \frac{\sin\frac{\alpha\pi}{2}}{\pi} x^{\frac{\alpha}{2}} \int_{0}^{\infty} \frac{d\xi}{\xi^{\frac{\alpha}{2}} (\xi+1)(1+(1-x)\xi)^{\frac{\alpha}{2}}}, & 0 < \alpha < 2, \\ x, & \alpha = 2. \end{cases}$$
(66)

So the limit random variable in law of (62) is given by  $(U_2/U_1) \wedge 1$ .

**Proof.** Recall that  $\{\xi_+(t)\}_{t\geq 0}$  is defined from a symmetric stable process  $\{w_+(t)\}_{t\geq 0}$  of exponent  $\alpha_+$  by  $\xi_+(t) = t + \underline{w}_+((\overline{w}_+)^{-1}(t))$  where  $\overline{w}_+(t) = \sup_{0\leq u\leq t} w_+(u)$  and  $\underline{w}_+(t) = \sup_{0\leq u\leq t} (-w_+(u))$ . Also,  $\{\xi_-(t)\}$  is defined from  $\{w_-(t)\}_{t\geq 0}$  in the same way. Denoting by  $\{x(t), P_a\}$  the stable process of index  $\alpha_+$  starting at  $a \in \mathbb{R}$  and by  $\sigma_b$  the first leaving time from the interval (-b, b);  $\sigma_b = \inf\{t>0| |x(t)|\geq b\}$  for b>0, we have for x>t>0,

$$P(\xi_{+}(t) \ge x) = P\left(\underline{w_{+}}((\overline{w_{+}})^{-1}(t)) \ge x - t\right)$$
$$= P_{\frac{x}{2}-t}\left(x(\sigma_{\frac{x}{2}}) \in (-\infty, -x/2]\right).$$
(67)

We have a general formula (cf. [2]): If |a| < b,

$$P_a(x(\sigma_b) \in dy) = \begin{cases} 1_{\{|y| > b\}} \cdot \frac{\sin \frac{\alpha_+ \pi}{2}}{\pi} \frac{(b^2 - a^2)^{\frac{\alpha_+}{2}}}{(y^2 - b^2)^{\frac{\alpha_+}{2}}} \cdot \frac{dy}{|y - a|}, & 0 < \alpha_+ < 2, \\ \frac{a + b}{2b} \delta_b(dy) + \frac{b - a}{2b} \delta_{-b}(dy), & \alpha_+ = 2. \end{cases}$$

Using this formula, we can easily calculate the RHS of (67) to obtain

$$P(\xi_+(t) \ge x) = u_{\alpha_+}\left(\frac{t}{x}\right), \quad 0 < t < x,$$

where  $u_{\alpha}(x)$ , 0 < x < 1, is given by (66). Hence

$$P\left(\frac{1}{\xi_+(t)} \le x\right) = u_{\alpha_+}(tx), \quad 0 < x < \frac{1}{t}.$$
(68)

By the self-similarity of stable processes, it is easy to deduce under  $P_{\alpha_+,\alpha_-}$ that  $\{\xi_{\pm}(ct)\}_{t\geq 0} \stackrel{d}{=} \{c\,\xi_{\pm}(t)\}_{t\geq 0}$ , respectively, for each c > 0. Then, noting the independence of  $\xi_+$  and  $\xi_-$ , we have under  $P_{\alpha_+,\alpha_-}$ ,

$$\xi_+((\xi_-)^{-1}(1)) \stackrel{d}{=} (\xi_-)^{-1}(1) \cdot \xi_+(1).$$

Also,

$$P\left((\xi_{-})^{-1}(1) \le x\right) = P(1 \le \xi_{-}(x)) = P\left(\frac{1}{\xi_{-}(x)} \le 1\right) = u_{\alpha_{-}}(x).$$

Therefore, setting  $U_1 = 1/\xi_+(1)$  and  $U_2 = (\xi_-)^{-1}(1)$ , we can now conclude the assertion of the theorem.  $\Box$ 

In the case of  $\alpha_{+} = \alpha_{-} = 2$ , in particular, the case of the Brox model, we have the following convergence:

$$P\left(\frac{1}{\log t}\log A(t) \le x\right) \longrightarrow \begin{cases} \frac{x}{2}, & 0 < x < 1, \\ 1, & x \ge 1, \end{cases} \quad as \ t \to \infty.$$
(69)

Note that p in (64) is given by

$$p = \int_{0}^{1} u_{\alpha_{+}}(x) \, du_{\alpha_{-}}(x).$$

When  $\alpha_+ = \alpha_-$ , we always have p = 1/2.

#### 4.2. The case of random walks on $\mathbb{Z}$ .

Given a sequence  $\mathbf{p} = (p_i), i \in \mathbb{Z}$ , such that  $0 < p_i < 1$ , let  $Z = (Z(n), P_i^Z)$  be a time-homogeneous Markov chain on  $\mathbb{Z}$  with the discrete time n = 0, 1, 2, ...and with the one-step transition probability  $p_{i,j}, i, j \in \mathbb{Z}$  given by

$$p_{i,j} = p_i \cdot \delta_{j,i+1} + (1 - p_i) \cdot \delta_{j,i-1}.$$
(70)

 $P_i^Z$  is the probability law governing the paths starting at *i* so that  $P_i^Z(Z(0) = i) = 1$  and  $P_i(Z(n+1) = j | Z(1), \ldots, Z(n)) = p_{Z(n),j}, j \in \mathbb{Z}$ . We denote it as  $Z^{\mathbf{p}} = (Z(n), P_i^{Z, \mathbf{p}})$  when we emphasize its dependence on  $\mathbf{p} = (p_i)$ .

As is well-known, Z can be imbedded in a birth and death process on  $\mathbb{Z}$  which is a generalized diffusion process associated with the Feller generator  $\mathcal{L} = \frac{d}{dm} \frac{d}{ds}$ with the speed measure dm supported on  $\mathbb{Z}$ . Here, the scale s(x) and the speed measure dm(x) are given as follows:

$$\begin{cases} s(0) = 0, \quad s(l) = \sum_{k=0}^{l-1} \prod_{i=0}^{k} \frac{1-p_i}{p_i}, & l = 1, 2, \dots, \\ s(-1) = -1, \quad s(l) = -1 - \sum_{k=1}^{-l-1} \prod_{i=1}^{k} \frac{p_{-i}}{1-p_{-i}}, & l = -2, -3, \dots \end{cases}$$
(71)

and s(x),  $-\infty < x < \infty$ , is given by the piecewise linear continuous extension;

$$s(x) = s(l) + (s(l+1) - s(l))(x - l), \quad l < x < l + 1.$$

The speed measure dm(x) is defined by setting

$$m(x) = \begin{cases} \sum_{k=0}^{l} \frac{1}{p_k} \prod_{i=0}^{k} \frac{p_i}{1-p_i}, & l \le x < l+1, \quad l = 0, 1, 2, \dots \\ 0, & -1 \le x < 0, \\ -\sum_{k=1}^{-l} \frac{1}{1-p_{-k}} \prod_{i=1}^{k} \frac{1-p_{-i}}{p_{-i}}, & l-1 \le x < l, \ l = -1, -2, \dots, \end{cases}$$
(72)

so that

$$dm(x) = \sum_{k=0}^{\infty} \frac{1}{p_k} \prod_{i=0}^k \frac{p_i}{1-p_i} \delta_k(dx) + \sum_{k=1}^{\infty} \frac{1}{1-p_{-k}} \prod_{i=1}^k \frac{1-p_{-i}}{p_{-i}} \delta_{-k}(dx).$$

We assume that  $\lim_{x\to\infty} s(x) = -\lim_{x\to-\infty} s(x) = \infty$ . Then, with the Feller generator  $\frac{d}{dm} \frac{d}{ds}$ , a unique recurrent generalized diffusion  $X = (X(t), P_i^X)$  is associated on the support of dm, which is  $\mathbb{Z}$  in this case, so that X is a birth and death process on  $\mathbb{Z}$ . We denote it as  $X^{\mathbf{p}} = (X(t), P_i^{X, \mathbf{p}})$  when we emphasize its dependence on  $\mathbf{p}$ . If  $\sigma_n$  is the *n*-th jumping time of X(t), then

$$(X(\sigma_n), P_i^X)_{n=0,1,2,\dots} \stackrel{d}{=} (Z(n), P_i^Z)_{n=0,1,2,\dots}.$$

Also, it is easy to see that the family  $\{\sigma_n - \sigma_{n-1}, n = 1, 2, ...\}$  is i.i.d. with mean 1 exponential distribution, so that, by the strong law of large numbers, we have

$$P_i^X\left(\text{for every } t_0 > 0, \ \sup_{t_0 \le t < \infty} \left|\frac{\sigma_{[e^{\lambda t}]}}{e^{\lambda t}} - 1\right| \to 0 \quad \text{as } \lambda \to \infty\right) = 1.$$
(73)

Here [x] denotes the largest integer not exceeding x: [x] = n if  $n \le x < n+1$ ,  $n \in \mathbb{Z}$ .

We define  $\xi_i, i \in \mathbb{Z}$ , by

$$\xi_i = \begin{cases} \log \frac{1 - p_i}{p_i}, & i = 0, 1, 2, \dots \\ \log \frac{p_i}{1 - p_i}, & i = -1, -2, \dots \end{cases}$$
(74)

Also, we define two càdlàg functions  $\theta_+(x)$  and  $\theta_-(x)$  on  $[0,\infty)$  by setting

$$\theta_{+}(x) = \sum_{i=0}^{|x|} \xi_{i}, \quad 0 \le x < \infty$$
(75)

and

$$\theta_{-}(x) = \begin{cases} 0, & 0 \le x < 1\\ \sum_{i=1}^{[x]} \xi_{-i}, & 1 \le x < \infty. \end{cases}$$
(76)

We extend  $\theta_{\pm}$  to be defined on  $\mathbb{R}$  by setting  $\theta_{\pm}(x) = 0$ , x < 0. We put the following assumption (A.4) on the sequence  $\mathbf{p} = (p_i)$ :

(A.4) There exist two càdlàg functions  $w_+(x) \in W_+$  and  $w_-(x) \in W_+$  on  $[0, \infty)$ , and two positive increasing functions  $\psi_+(\lambda)$  and  $\psi_-(\lambda)$  of  $\lambda > 0$  with  $\lim_{\lambda \to \infty} \psi_{\pm}(\lambda) = \infty$ , such that the following convergence holds:

$$\left(\frac{1}{\lambda}\theta_{+}(\psi_{+}(\lambda)t), \frac{1}{\lambda}\theta_{-}(\psi_{-}(\lambda)t)\right) \longrightarrow (w_{+}(t), w_{-}(t)) \quad \text{as} \quad \lambda \to \infty \quad (77)$$

in the sense of Skorohod's  $J_1$ -topology on  $W_+ \times W_+$ . (For the definition on  $W_+$ , see the beginning of Subsection 4.1)

We define continuous increasing functions  $s_+(x)$  and  $s_-(x)$  of  $x \in [0, \infty)$  by

$$s_{\pm}(x) = \int_{0}^{x} e^{\theta_{\pm}(u)} \, du, \quad x \ge 0.$$
(78)

We also define càdlàg increasing functions  $m_+(x)$  and  $m_-(x)$  of  $x \in [0, \infty)$  by

$$m_{+}(x) = \int_{0}^{[x]+1} e^{-\theta_{+}(u)} du + \int_{0}^{[x]+1} e^{-\theta_{+}(u-1)} du, \quad x \ge 0$$
(79)

and

$$m_{-}(x) = \int_{0}^{[x]} e^{-\theta_{-}(u)} du + \int_{0}^{[x]} e^{-\theta_{-}(u+1)} du, \quad x \ge 0.$$
(80)

We can easily verify from (71) and (72) that

$$s(x) = s_+(x), \quad m(x) = m_+(x) \quad \text{for } x \ge 0,$$
(81)

and

$$s(x) = -s_{-}(-x), \quad m(x) = -m_{-}(-x-0) \quad \text{for } x < 0:$$
 (82)

In verifying the identities  $m(x) = m_+(x)$  for  $x \ge 0$  and  $m(x) = -m_-(-x-0)$  for x < 0, note the simple relations  $\frac{1}{p_k} = \frac{1-p_k}{p_k} + 1$ ,  $k = 0, 1, \ldots$  and  $\frac{1}{1-p_{-k}} = \frac{p_{-k}}{1-p_{-k}} + 1$ ,  $k = 1, 2, \ldots$ 

We now set, for  $\lambda > 0$  and each of + and -,

$$s_{\lambda}^{\pm}(x) = s_{\pm}(\psi_{\pm}(\lambda) x), \quad x \ge 0, \tag{83}$$

$$m_{\lambda}^{\pm}(x) = m_{\pm}(\psi_{\pm}(\lambda) x), \quad x \ge 0, \tag{84}$$

$$w_{\lambda}^{\pm}(x) = \frac{1}{\lambda} \theta_{\pm}(\psi_{\pm}(\lambda) x), \quad x \ge 0,$$
(85)

$$v_{\lambda}^{+}(x) = \frac{1}{\lambda} \theta_{+}(\psi_{+}(\lambda) x - 1), \quad x \ge 0,$$
(86)

$$v_{\lambda}^{-}(x) = \frac{1}{\lambda} \theta_{-}(\psi_{-}(\lambda) x + 1), \quad x \ge 0,$$
(87)

$$\varphi_{\lambda}^{+}(x) = \frac{\left[\psi_{+}(\lambda) x\right] + 1}{\psi_{+}(\lambda)}, \quad x \ge 0$$
(88)

and

$$\varphi_{\lambda}^{-}(x) = \frac{\left[\psi_{-}(\lambda) x\right]}{\psi_{-}(\lambda)}, \quad x \ge 0.$$
(89)

Then, it easy to deduce from (78), (79) and (80) that, for each of + and -,

$$s_{\lambda}^{\pm}(x) = \psi_{\pm}(\lambda) \cdot \int_{0}^{x} e^{\lambda w_{\lambda}^{\pm}(u)} du$$

and

$$m_{\lambda}^{\pm}(x) = \psi_{\pm}(\lambda) \cdot \int_{0}^{\varphi_{\lambda}^{\pm}(x)} \left\{ e^{-\lambda w_{\lambda}^{\pm}(u)} + e^{-\lambda v_{\lambda}^{\pm}(u)} \right\} du.$$

(77) implies that

$$(w_{\lambda}^{+}(t), w_{\lambda}^{-}(t)) \longrightarrow (w_{+}(t), w_{-}(t))$$

and

$$(v_{\lambda}^+(t), v_{\lambda}^-(t)) \longrightarrow (w_+(t), w_-(t))$$

as  $\lambda \to \infty$  in the J<sub>1</sub>-topology on  $W_+ \times W_+$ .

Thus, our family defined above satisfies the conditions in Examp. 14 so that we have the same conclusion for the occupation time  $A_{\lambda}(t) = \int_0^t \mathbb{1}_{[0,\infty)}(X_{\lambda}(u)) \, du$ 

where  $X_{\lambda} = (X_{\lambda}(t))$  is  $\mathcal{L}_{\lambda} = \frac{d}{dm_{\lambda}} \frac{d}{ds_{\lambda}}$ -generalized diffusion. Here, noting (78), (79) and (80) combined with (83) and (84), we have  $s_{\lambda} = s \circ T_{\psi_{+}(\lambda),\psi_{-}(\lambda)}$  and  $m_{\lambda} = m \circ T_{\psi_{+}(\lambda),\psi_{-}(\lambda)}$ , where the map T is defined, as above, by  $T_{a,b}(x) = ax \mathbf{1}_{\{x>0\}} + bx \mathbf{1}_{\{x<0\}}$ . Hence,

$$X_{\lambda}(t) \stackrel{d}{=} T^{-1}_{\psi_{+}(\lambda),\psi_{-}(\lambda)} \circ X(t) \left( = T_{1/\psi_{+}(\lambda),1/\psi_{-}(\lambda)}(X(t)) \right)$$

from the birth and death process  $X = (X(t), P_i^X)$  introduced at the beginning of this subsection.

This conclusion can be applied, in the same way as we did in the previous Subsection 4.1, to the study of the occupation time for the birth and death processes in random environment and thereby for random walk in random environment.

First of all, we set up our model. Let  $\Pi$  be the totality of sequences  $\mathbf{p} = (p_i), i \in \mathbb{Z}$ , such that  $0 < p_i < 1$  and  $\lim_{x\to\infty} s(x) = -\lim_{x\to-\infty} s(x) = \infty$ , where s(x) is defined as above by (71). For  $\mathbf{p} \in \Pi$ , we have the random walk  $Z^{\mathbf{p}} = (Z(n), P_i^{Z, \mathbf{p}})$  on  $\mathbb{Z}$  as above which we realize canonically on  $\Omega_{\mathbb{Z}}^{(1)} = \{\omega : \mathbb{Z}_+ \ni n \mapsto \omega(n) \in \mathbb{Z}\}$  so that  $Z(n) = \omega(n), \omega \in \Omega_{\mathbb{Z}}^{(1)}$  and  $P_i^{Z, \mathbf{p}}$  is the probability on  $\Omega_{\mathbb{Z}}^{(1)}$  supported on  $\{\omega : \omega(0) = i\}$ . Here, we use the notation  $\mathbb{Z}_+ = \{0, 1, 2, \ldots\}$  and  $\mathbb{Z}_- = \{-1, -2, \ldots\}$  so that  $\mathbb{Z} = \mathbb{Z}_+ \cup \mathbb{Z}_-$ . A random walk in random environment is determined by giving a probability P on  $\Pi$ ; we realize this on  $\Omega_{\mathbb{Z}}^{(1)} \times \Pi$  with the annealed probability  $\overline{P}_i^Z(d\omega d\mathbf{p}) = P(d\mathbf{p}) P_i^{Z,\mathbf{p}}(d\omega)$ , so that  $P_i^{Z,\mathbf{p}}$  can be regarded as the conditional probability given the environment  $\mathbf{p}$ .

In the same way, for given  $\mathbf{p} \in \Pi$ , we have the birth and death process  $X^{\mathbf{p}} = (X(t), P_i^{X, \mathbf{p}})$  on  $\mathbb{Z}$ , which we realize on  $\Omega_{\mathbb{Z}}^{(2)} = \{\omega : [0, \infty) \ni t \mapsto \omega(t), \text{ càdlàg }\}$  as  $X(t) = \omega(t), \omega \in \Omega_{\mathbb{Z}}^{(2)}$  and  $P_i^{X, \mathbf{p}}$  is the law of  $\frac{d}{dm} \frac{d}{ds}$ - generalized diffusion starting at *i* with *s* and *m* defined by (71) and (72), which is a probability on  $\Omega_{\mathbb{Z}}^{(2)}$  supported on  $\{\omega : \omega(0) = i\}$ . The birth and death process in random environment is defined by the probability  $\overline{P}_i^X(d\omega d\mathbf{p}) = P(d\mathbf{p}) P_i^{X, \mathbf{p}}(d\omega)$ .

We put, in accordance with the assumption (A.4) above, the following fundamental assumption (A.5) on the probability P on  $\Pi$ :

(A.5) Under P on  $\Pi$ ,  $\mathbf{p} = (p_i)$  satisfies the following; the families  $\mathbf{p}_+ := \{p_0, p_1, \ldots\}$ and  $\mathbf{p}_- := \{p_{-1}, p_{-2}, \ldots\}$  are mutually independent i.i.d. families. Furthermore, there exist two constants  $0 < \alpha_+ \le 2$  and  $0 < \alpha_- \le 2$ , two positive increasing functions  $\psi_+(\lambda)$  and  $\psi_-(\lambda)$  of  $\lambda > 0$  with  $\lim_{\lambda \to \infty} \psi_{\pm}(\lambda) = \infty$ such that the following convergence holds:

$$\left(\frac{1}{\lambda}\theta_{+}(\psi_{+}(\lambda)t), \frac{1}{\lambda}\theta_{-}(\psi_{-}(\lambda)t)\right) \xrightarrow{d} (w_{+}(t), w_{-}(t)) \text{ as } \lambda \to \infty$$
(90)

in the sense of  $J_1$ -topology on  $W_+ \times W_+$ , where  $\{w_+(t)\}$  and  $\{w_-(t)\}$  are

mutually independent symmetric stable processes of exponent  $\alpha_+$  and  $\alpha_-$ , respectively.

Here, càdlàg increasing processes  $\theta_+(t)$  and  $\theta_-(t)$  are defined from  $\mathbf{p} = (p_i)$  by (74), (75) and (76).

A standard sufficient condition for (A.5) to hold is that, denoting by  $p_+$  and  $p_-$  the common random variables in law of the i.i.d. families  $\mathbf{p}_+$  and  $\mathbf{p}_-$ , respectively, the following hold for each of + and -:

 $0 < p_{\pm} < 1, p_{\pm} \stackrel{d}{=} 1 - p_{\pm}$  and, setting  $\xi_{\pm} = \log\{(1 - p_{\pm})/p_{\pm}\}, E[(\xi_{\pm})^2 \cdot 1_{\{0 < \xi_{\pm} < x\}}]$  is a slowly varying function of x at  $\infty$  when  $\alpha_{\pm} = 2$ , and  $P(\xi_{\pm} > x)$  is a regularly varying function of x at  $\infty$  with exponent  $-\alpha_{\pm}$  when  $0 < \alpha_{\pm} < 2$ . Note that, under our assumption (A.5),  $\limsup_{x\to\infty} \theta_{\pm}(x) = \infty$  and  $\lim_{x\to\pm\infty} s(x) = \pm\infty$  almost surely.

Now, for almost all  $\mathbf{p} \in \Pi$ , we can define, for  $\lambda > 0$  and each of + and -,  $s_{\lambda}^{\pm}, m_{\lambda}^{\pm}, w_{\lambda}^{\pm}, v_{\lambda}^{\pm}, \varphi_{\lambda}^{\pm}$  as above through (83) to (89). From  $s_{\lambda}^{\pm}$  and  $m_{\lambda}^{\pm}$ , càdlàg increasing functions  $s_{\lambda}(x)$  and  $m_{\lambda}(x)$  on  $\mathbb{R}$  are defined as in Example 14 and the unique recurrent generalized diffusion  $X^{\lambda} = (X^{\lambda}(t), P_{x}^{\lambda})$  is associated with the Feller generator  $\mathcal{L}_{\lambda} = \frac{d}{dm_{\lambda}} \frac{d}{ds_{\lambda}}$ . As we remarked above,  $X^{\lambda}$  is obtained from  $X^{\mathbf{p}} = (X(t), P_{i}^{X, \mathbf{p}})$  by  $\{X^{\lambda}(t)\} \stackrel{d}{=} \{T_{1/\psi_{+}(\lambda), 1/\psi_{-}(\lambda)}(X(t))\}$  so that the state space of  $X^{\lambda}$  is  $\frac{1}{\psi_{+}(\lambda)}\mathbb{Z}_{+} \cup \frac{1}{\psi_{-}(\lambda)}\mathbb{Z}_{-}$ . Define

$$A_{\lambda}(t) = \int_{0}^{t} 1_{[0,\infty)}(X^{\lambda}(s)) \, ds$$
 and  $A^{X}(t) = \int_{0}^{t} 1_{[0,\infty)}(X(s)) \, ds.$ 

Then obviously

$$\{A_{\lambda}(t), \overline{P}_{0}^{\lambda}\} \stackrel{d}{=} \{A^{X}(t), \overline{P}_{0}^{X}\}$$

where  $\overline{P}_0^{\lambda}(d\omega \, d\mathbf{p}) = P(d\mathbf{p}) P_0^{\lambda}(d\omega)$ . For  $A_{\lambda}(t)$ , we can apply the result of Example 14 with Remark 3.1 and, using this result, we can give the same arguments as in Subsection 4.1 to obtain the following:

# **Theorem 24** Under $\overline{P}_0^X$ ,

$$\left\{\frac{1}{\lambda}\log A^X(e^{\lambda t})\right\}_{t\geq 0} \longrightarrow \left\{\xi_+((\xi_-)^{-1}(t))\wedge t\right\}_{t\geq 0}, \quad as \ \lambda \to \infty \tag{91}$$

in the sense of convergence of all finite-dimensional distributions as well as the convergence in law as  $\Phi$ -valued random variables. In particular

$$\frac{1}{\log t} \log A^X(t) \xrightarrow{d} \xi_+((\xi_-)^{-1}(1)) \wedge 1 \quad as \ t \to \infty.$$
(92)

Here, the processes  $\xi_+$  and  $\xi_-$  are defined from independent symmetric stable processes  $w_+$  and  $w_-$  in the same way as in Theorem 20, namely by (53) and (55), and the limit law in (92) is given in the same way as Theorem 23.

We can now deduce from this our final result for the random walk in the random environment  $Z = (Z(n), \overline{P}_i^Z)$ .

**Theorem 25** Let 
$$A^{Z}(n) = \sum_{k=1}^{n} \mathbb{1}_{\{Z(k-1) \ge 0, Z(k) \ge 0\}}$$
. Then, under  $\overline{P}_{0}^{Z}$ ,  
 $\left\{\frac{1}{\lambda} \log A^{Z}([e^{\lambda t}])\right\}_{t \ge 0} \longrightarrow \left\{\xi_{+}((\xi_{-})^{-1}(t)) \land t\right\}_{t \ge 0}, \quad as \ \lambda \to \infty$ (93)

in the sense of convergence of all finite-dimensional distributions as well as the convergence in law as  $\Phi$ -valued random variables. In particular,

$$\frac{1}{\log n} \log A^Z(n) \stackrel{d}{\longrightarrow} \xi_+((\xi_-)^{-1}(1)) \wedge 1 \quad as \ n \to \infty.$$
(94)

Here, the processes  $\xi_+$  and  $\xi_-$  are defined from independent symmetric stable processes  $w_+$  and  $w_-$  by (53) and (55) so that the law of the limit random variable is given by Theorem 23.

**Proof.** For  $\mathbf{p} \in \Pi$ , let  $X^{\mathbf{p}} = (X(t), P_i^{X, \mathbf{p}})$  be the birth and death process on  $\mathbb{Z}$  as given above realized on the space  $\Omega_{\mathbb{Z}}^{(2)}$ . It is a  $\frac{d}{dm}\frac{d}{ds}$ -generalized diffusion process where s(x) and m(x) are defined by (82) through  $\mathbf{p}$ . We assume  $\mathbf{p}$  possesses the property that both  $\lim_{x\to\infty} s(x) = \lim_{x\to-\infty} (-s(x)) = \infty$  and  $\lim_{x\to\infty} m(x) = \lim_{x\to-\infty} (-m(x)) = \infty$  hold. We note that almost every  $\mathbf{p} \in \Pi$  under  $P(d\mathbf{p})$  possesses this property.

Let  $\sigma_n, n = 0, 1, 2, \ldots$ , be the *n*-th jumping time of X(t):

$$\sigma_0 = 0, \quad \sigma_n = \inf\{t > \sigma_{n-1} | X(t) \neq X(\sigma_{n-1})\}, \quad n = 1, 2, \dots$$
(95)

Set

$$Z(n) = X(\sigma_n), \quad n = 0, 1, \dots$$
(96)

and

$$\tau_n = \sigma_n - \sigma_{n-1}, \quad n = 1, 2, \dots$$
(97)

Then  $\{Z(n)\}$  under  $P_i^{X,\mathbf{p}}$  is a realization of the random walk (in a fixed environment  $\mathbf{p}$ ) such that Z(0) = i. Note that  $\{\tau_n\}$  is i.i.d. with mean 1 exponential distribution. Also,  $\{X(\sigma_n)\}$  and  $\{\sigma_n\}$  are independent.

In the following, we consider under the probability  $P_0^{X,\mathbf{p}}$ . Set, as above,

$$A^{Z}(n) = \sum_{k=1}^{n} \mathbb{1}_{\{Z(k-1) \ge 0, Z(k) \ge 0\}}, \quad n = 1, 2, \dots,$$
(98)

and also

$$A(n) = \sum_{k=1}^{n} \mathbb{1}_{\{Z(k-1) \ge 0\}}, \quad n = 1, 2, \dots,$$
(99)

$$A^{X}(t) = \int_{0}^{t} \mathbb{1}_{[0,\infty)}(X(s)) \, ds.$$
(100)

Then, we have

$$A^{X}(\sigma_{n}) = \sum_{k=1}^{n} \mathbb{1}_{\{Z(k-1) \ge 0\}} \cdot \tau_{k}$$
(101)

and hence

$$\frac{A^X(\sigma_n)}{A(n)} = \frac{\sum_{k=1}^n \tau_k \, \mathbf{1}_{\{Z(k-1) \ge 0\}}}{\sum_{k=1}^n \mathbf{1}_{\{Z(k-1) \ge 0\}}}$$

Let a random sequence  $\{k_i\}$  of positive integers be defined, successively, by

$$k_1 = 1, \quad k_i = \min\{k > k_{i-1} | Z(k-1) \ge 0\}, \quad i = 2, 3, \dots$$

Since  $X^{\mathbf{p}}$  is recurrent,  $\{k_i\}$  is well-defined *a.s.*. Set  $\theta_i = \tau_{k_i}$ ,  $i = 1, 2, \ldots$  By the strong Markov property of  $X^{\mathbf{p}}$ , we can easily deduce that  $\{\theta_i\}$  is also i.i.d. with mean 1 exponential distribution. Obviously, we have

$$A^X(\sigma_n) = \theta_1 + \theta_2 + \ldots + \theta_i$$
 and  $A(n) = i$  if  $k_i \le n < k_{i+1}$ .

Hence, by the strong law of large numbers, the following convergence occurs almost surely:

$$\frac{A^X(\sigma_n)}{A(n)} = \frac{\theta_1 + \theta_2 + \ldots + \theta_i}{i} \longrightarrow 1, \quad \text{as } n \to \infty.$$

Thus we have

$$A(n) = A^X(\sigma_n)(1+o(1)) \quad \text{as } n \to \infty \ a.s..$$
(102)

If we set  $\tilde{a}(n) = \int_0^{\sigma_n} \mathbb{1}_{\{0\}}(X(s)) ds$ , then  $\tilde{a}(n) = \sum_{k=1}^n \tau_k \mathbb{1}_{\{Z(k-1)=0\}}$  and, by the same argument as for the proof of (102), we have

$$a(n) = \tilde{a}(n)(1+o(1))$$
 as  $n \to \infty$  a.s.,

where  $a(n) = \sum_{k=1}^{n} 1_{\{Z(k-1)=0\}}$ . Since

$$A(n) - A^{Z}(n) = \sum_{k=1}^{n} \mathbb{1}_{\{Z(k-1) \ge 0, Z(k) < 0\}}$$
  
=  $\sum_{k=1}^{n} \mathbb{1}_{\{Z(k-1) \ge 0, Z(k) \ge -1\}} \le \sum_{k=1}^{n} \mathbb{1}_{\{Z(k-1) \ge 0\}} = a(n),$ 

we have

$$0 \le A(n) - A^Z(n) \le \tilde{a}(n) \left(1 + o(1)\right) \quad \text{as } n \to \infty \ a.s.. \tag{103}$$

Finally, we have

$$\widetilde{a}(n) = o(A^X(\sigma_n)) \quad \text{as } n \to \infty \ a.s..$$
(104)

This follows from the well-known ratio ergodic theorem for a recurrent  $\frac{d}{dm}\frac{d}{ds}$ generalized diffusion X(t) on  $\mathbb{R}$ , which states that, if  $B_1$  and  $B_2$  are Borel subsets of  $\mathbb{R}$  such that  $0 < \widetilde{m}(B_1) < \infty$  and  $0 < \widetilde{m}(B_2) \le \infty$ , then

$$\frac{\int_0^t 1_{B_1}(X(s)) \, ds}{\int_0^t 1_{B_2}(X(s)) \, ds} \longrightarrow \frac{\widetilde{m}(B_1)}{\widetilde{m}(B_2)} \quad \text{as } t \to \infty, \ a.s.$$

where  $\widetilde{m}(dx) = d(m \circ s^{-1}(x))$ , (cf. [8]).

Note that, in our case,

$$\frac{\widetilde{a}(n)}{A^X(\sigma_n)} = \frac{\int_0^{\sigma_n} 1_{\{0\}}(X(s))ds}{\int_0^{\sigma_n} 1_{[0,\infty)}(X(s))ds},$$
  
and  $\widetilde{m}(\{0\}) < \infty$  but  $\widetilde{m}([0,\infty)) = \infty.$ 

From (102), (103) and (104), we have

$$A^{Z}(n) = A^{X}(\sigma_{n}) (1 + o(1))$$
 as  $n \to \infty$ , a.s.

for  $P_0^{X,\mathbf{p}}$  and hence, *a.s.* for  $\overline{P}_0^X$ . We can now deduce the convergence (93) from the convergence (91) combined with (73).  $\Box$ 

In the same way as Corollary 21, we have the following

**Corollary 26** Under  $\overline{P}_0^Z$ ,

$$\frac{A^{Z}(n)}{n} \xrightarrow{d} 1_{\{(\xi_{+})^{-1}(1) < (\xi_{-})^{-1}(1)\}} \quad as \ n \to \infty.$$
