ABSTRACT

[Purpose] Tumor microenvironment (TME) including the immune checkpoint system impacts prognosis in some types of malignancy. The aim of our study was to investigate the precise prognostic significance of the TME profile in endometrial carcinoma.

[Materials and methods] We performed immunohistochemistry of the TME proteins, PD-L1, PD-1, CD4, CD8, CD68, and VEGF in endometrial carcinomas from 221 patients who received surgery in the Department of Obstetrics and Gynecology at the University of Tsukuba Hospital between 1999 and 2009.

[Results] High PD-L1 in tumor cells (TCs) was associated with better overall survival (OS) (p = 0.004), whereas high PD-L1 in tumor-infiltrating immune cells (TICs) was associated with worse OS (p = 0.02). High PD-L1 in TICs correlated with high densities of CD8+ TICs and CD68+ TICs, as well as microsatellite instability (MSI) (p = 0.00000064, 0.00078, and 0.0056), while high PD-L1 in TCs correlated with longer treatment-free interval (TFI) after primary chemotherapy in recurrent cases (p = 0.000043). High density of CD4+ TICs correlated with better OS and longer TFI (p = 0.00008 and 0.014). Univariate and multivariate analyses of prognostic factors revealed that high PD-L1 in TCs and high density of CD4+ TICs were significant and independent for favorable OS (p = 0.014 and 0.0025).

[Discussion] High PD-L1 expression in TICs showed an inverse correlation with high PD-L1 expression in TCs, and those expressions exhibited opposite prognostic associations for OS. These observations may be explicable if some proportion of expressed PD-L1 could move between the surface of TCs and the surface of TICs so that the PD-L1 bound to PD-1 on the surface of TICs may induce adaptive immune resistance leading to poor survival, while the PD-L1 remaining on the surface of TCs may not. This hypothesis may be supported by the published findings that, in addition to tissue PD-L1, there also exist circulating PD-L1 such as exosomal PD-L1 and soluble PD-L1. Further molecular and clinical investigations are essential to verify our observation and to elucidate the mechanism underlying them.

High PD-L1 expression in TICs was associated with MSI, and with high density of CD8+ TICs and CD68+ TICs, suggesting that PD-L1-induced adaptive immune resistance may involve MSI, killer T cells. MSI is known to cause hypermutation leading to increased burden of tumor antigens, which induces increased immune response. Increased immune response may induce PD-1/PD-L1-mediated adaptive immune resistance, which will lead to aggressive tumor phenotype and poor prognosis. Taken together, these findings suggest that PD-L1 expression of TICs may be a biomarker for the T cell-inflamed tumor phenotype. Clinical response to anti-PD-1

monoclonal antibody was reported to occur almost exclusively in patients with pre-existing T cell infiltrates in the region of PD-L1 upregulation. Following anti-PD-1 administration, these CD8+ T cells seemed to proliferate and expand to penetrate throughout the tumor, which correlated with tumor regression. Altogether, our findings implicate that anti-PD-1/PD-L1 therapy may improve the unfavorable survival of the subset of endometrial cancers with TICs expressing high PD-L1.

Moreover, in the analysis of the associations between the TME protein expressions and TFI after primary adjuvant chemotherapy, high PD-L1 expression in TCs indicated a longer TFI, suggesting that prognostic impact of PD-L1 expression may be mediated by affected chemosensitivity. This hypothesis may be supported by the published findings where upregulation of the PD-1/PD-L1 axis confers chemoresistance in some types of tumor. Accordingly, our findings further suggest that anti-PD-1/PD-L1 therapy may attenuate chemoresistance in the patients with TICs expressing high PD-L1.

In the univariate and multivariate analyses of prognostic factors, high density of CD4+ TICs was also found to be significant and independent for favorable OS. Besides, high density of CD4+ TICs was found to be associated with longer TFI, suggesting that helper T cells also may affect prognosis through involving chemosensitivity.

Our findings indicate that anti-PD1/PD-L1 therapies combined with conventional

chemotherapeutics may be beneficial for the patients with poor prognosis due to high PD-L1 expression in TICs through improving chemosensitivity.

[Conclusion] The current findings indicate that PD-L1 and CD4+ helper T cells may be reasonable targets for improving survival through manipulating chemosensitivity, providing significant implications for combining immunotherapies into the therapeutic strategy for endometrial carcinoma. Further studies are warranted to clarify the clinical and prognostic significance of the TME status in endometrial cancer.

1. INTRODUCTION

Endometrial cancer is the most common malignancy of female reproductive organs in developed countries, and the incidence is recently increasing.[1] Primary treatment comprises surgery in combination with adjuvant chemotherapy and/or radiotherapy based on the risk stratification for recurrence. The majority of cases are diagnosed at an early stage, and the 5-year survival rate for those with localized disease is 95%.[2] Yet 15–20% of these tumors recur after primary treatment.[3] The 5-year survival rate for those with advanced/recurrent measurable disease is <10%, and the efficacy of second-line chemotherapy after primary regimens with taxane plus platinum is not more than 15%.[4] Thus, development of novel treatment strategy for those diseases is urgently required.

Programmed cell death-1 (PD-1), immune inhibiting receptor, is expressed on the surface of activated T cells and B cells, and the PD-1 pathway plays critical roles in maintaining immunological self-tolerance.[5] There are two ligands for this receptor, programmed cell death-ligand 1 (PD-L1) and PD-L2. PD-L2 is expressed on activated dendritic cells and macrophages predominantly as well as on tumor cells and B cells, while PD-L1 is expressed on many cell types including immune cells and tumor cells.[6] Tumor cells escape host antitumor immune response through the PD-1/PD-L1

pathway. Recently, therapeutics targeting this immune checkpoint system have shown unprecedented durable clinical responses in various kinds of tumor.[7]

A study by Teng et al. on advanced malignant melanomas showed that tumor microenvironment (TME) can be classified based on tumor infiltrating lymphocytes (TILs) and PD-L1 expression: PD-L1⁺ TIL⁺ group of tumors favorably responded to immune checkpoint blockade.[8] Another study on melanomas by Tumeh et al. showed that pre-existing CD8⁺ T cells located at the invasive tumor margin were associated with the expression of PD-1/PD-L1 immune inhibitory system and may predict response to anti-PD-L1 therapy.[7] Regarding ovarian cancer, a study by Webb et al. on high-grade serous ovarian cancer showed that PD-L1 expressed by tumor-associated macrophages (TAM) was significantly associated with favorable disease-specific survival after anti-PD-1 antibody therapy.[9] Darb-Esfahani et al. have shown that PD-1/PD-L1 expressions in high-grade serous ovarian cancer were significantly associated with favorable progression-free survival (PFS) and overall survival (OS).[10] Another study on ovarian cancer by Hamanishi et al. has shown that high PD-L1 expression on tumor cells and low CD8⁺ T lymphocyte count are independent prognostic factors for poor PFS and OS.[11] Colorectal cancers with microsatellite instability (MSI) were reported to lead to higher mutation burden, with a greater density

of CD8⁺ lymphocytes, and to benefit more from pembrolizumab, a kind of anti-PD-1 antibody.[12] Frequency of MSI in endometrial cancer is reportedly 22-33%, higher than cervical (8%) and ovarian (10%) cancers, being highest among gynecologic malignancies.[13] As regards endometrial cancer, the significance of the PD-1/PD-L1 pathway has just begun to be investigated including a number of ongoing clinical trials.[14] (Fig.1)

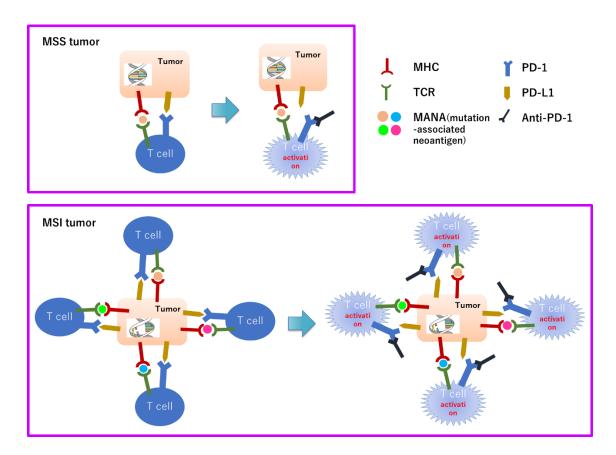

Fig. 1. Proposed relationship between MSI status and immunologic response.

There exist varieties of factors in the TME of endometrial carcinoma. The purpose of the current study is to find out the relationships between the TME profile including PD-1/PD-L1 expressions and clinicopathologic features, and to identify predictive biomarkers for the outcome by treatments. Our findings provide significant implications for formulating novel therapeutic strategy for the disease.[15]

2. MATERIALS AND METHODS

2.1 Patients and specimens

All patients diagnosed with endometrial carcinoma, who received surgery in the Department of Obstetrics and Gynecology at the University of Tsukuba Hospital between 1999 and 2009, were identified through our database. A total of consecutive 221 patients were included in the present study, and their medical records were retrospectively reviewed. All samples were obtained with opt-out procedure in accordance with the study protocol approved by the Ethics Committee University of Tsukuba Hospital (H26-118). The study was performed in accordance with the Declaration of Helsinki. A median follow-up duration was 132 months (range, 3–209 months). Follow-up data were retrieved until 2018-7-20. Staging was performed based on the criteria of International Federation of Gynecology and Obstetrics (FIGO, 2008).

Endometrioid carcinomas were subclassified into three grades (G1, G2, and G3) according to the FIGO criteria. Treatment of patients was described previously.[16] Table 1 summarizes the patient demographics.

BMC Cancer.

2.2 Immunohistochemistry

Immunohistochemical (IHC) procedures were conducted as described previously.[16] Antibodies used are PD-L1 (SP142, rabbit monoclonal, Spring Bioscience, Pleasanton, CA, USA), PD-1 (NAT105, mouse monoclonal, GeneTex, Irvine, CA, USA), CD4 (clone SP35, rabbit monoclonal, Spring Bioscience, Pleasanton, CA, USA), CD8 (clone C8/144B, mouse monoclonal, Nichirei Biosciences, Tokyo, Japan), CD68 (PG-M1, mouse monoclonal, DAKO, Tokyo, Japan), and VEGF (A-20, rabbit polyclonal, Santa Cruz, Dallas, TX, USA). For PD-L1 staining, antigen retrieval was done by autoclaving at 121°C for 10 min in Tris/EDTA buffer (pH 9.0), and 1st antibody incubation (1:100) was conducted at 4°C overnight. The corresponding normal endometria or stroma provided an internal positive control, and negative controls without addition of primary antibody showed low background staining.

2.3 IHC scoring

Blinded for clinical and pathologic parameters, immunoreaction was assigned by two investigators (Shuang Zhang and Takeo Minaguchi), and any discrepancies were resolved by conferring over a multiviewer microscope. For semiquantitative analyses for PD-L1 and VEGF, the IHC staining was scored by multiplying the percentages of positive tumor cells (PP: 0, no positive cell; 1, <10%; 2, 10–50%; and 3, >50% positive

tumor cells) by their prevalent degree of staining (SI: 0, no staining; 1, weak; 2, moderate; and 3, strong). The IHC scores (IHS=PP×SI) range from 0 to 9. For PD-L1, we evaluated membrane staining of tumor cells (TCs) and tumor-infiltrating immune cells (TICs) separately. For CD4, CD8, CD68, and PD-1, we counted positive TICs by magnification of ×200 in most abundant 3 locations of the slide and calculated the average. The representative images for immunostaining are shown in Fig. 2.

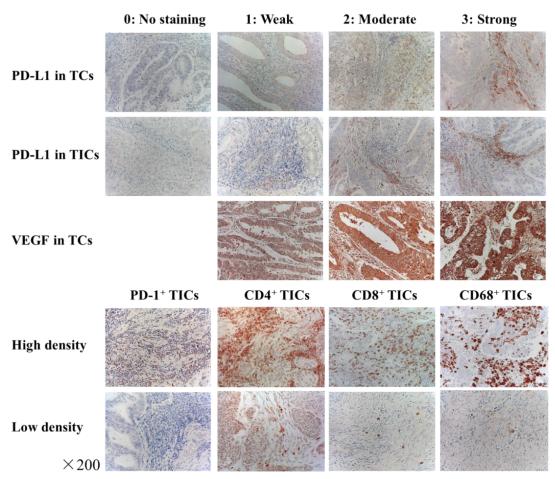

Fig. 2. Representative images for immunostaining.[15]

Zhang S, et al. BMC Cancer. 2020;20:127

2.4 MSI analysis

MSI status was analyzed with the five fluorescence-labeled microsatellite markers, BAT25, BAT26, D2S123, D5S346 and D17S250.[17] Tumors showing allelic shift at one or more markers were classified as MSI, and tumors with no allelic shift at any marker as microsatellite stable (MSS).

2.5 Statistical analyses

Differences in proportions were evaluated by the Fisher's exact test. Differences in continuous variables were evaluated by the Mann-Whitney U test. The optimal cut-off values of IHC scores for the relationship with OS were determined by the K-Adaptive partitioning method (Table 2)[18]. Kaplan–Meier survival curves were calculated and compared statistically using the log-rank test. The Cox proportional hazard model was used for the univariate and multivariate analyses. OS was measured from the start of primary treatment to death from any cause. Treatment-free interval (TFI) was measured from the end of primary adjuvant chemotherapy to the diagnosis of recurrence. Statistical analyses were performed using R version 3.5.3.

	Mean±SD	Min	Max	Cut-off	Category	N (%)
PD-L1 in TCs	1.36±1.47	0	9	0<	High expression Low expression	155(70) 66(30)
PD-L1 in TICs	2.70±1.94	0	9	4<	High expression Low expression	36(16) 185(84)
PD-1+ TICs	16.94±23.55	0	129.33	6.67<	High density Low density	131(59) 90(41)

3. RESULTS

We performed IHC evaluation of the TME proteins in 221 primary endometrial carcinomas (Table 2). First, we examined mutual relationships among the IHC results. High PD-L1 expression in TCs showed an inverse correlation with high PD-L1 expression in TICs (p=0.0054; Table 3). High PD-L1 expression in TICs correlated with high density of PD-1⁺, CD8⁺, and CD68⁺ TICs (p=0.00032, 6.4E-07, and 0.00078; Table 3). High density of CD8⁺, and CD68⁺ TICs (p=0.0097 and 0.00028; Table 3). High density of CD4⁺, CD8⁺, and CD68⁺ TICs showed mutual correlations (Table 3).

	PD-L1 in		D-L1 in TICs		PD-1 ⁺ TICs		VEGF in TCs		CD4 ⁺ TI		TICs		CD8 ⁺ TICs			CD68 ⁺ TICs		
	High (n=36)	Low (n=185)	P- value	High (n=131)	Low (n=90)	P-value	High (n=151)	Low (n=70)	P- value	High (n=117)	Low (n=104)	P- value	High (n=43)	Low (n=178)	P-value	High (n=129)	Low (n=92)	P-value
High PD-L1 in TCs	18 (50%)	137 (74%)	0.0054	88 (67%)	67 (74%)	0.30	102 (68%)	53 (76%)	0.27	86 (74%)	69 (66%)	0.30	33 (77%)	122 (69%)	0.36	88 (68%)	67 (73%)	0.55

Table 3. Mutual relationships among TME protein expressions.

Secondly, we examined the relationships between the IHC evaluations and clinicopathologic parameters (Table 4). High PD-L1 expression in TCs was associated with G1, non-G3, superficial myometrial invasion, and negative lymphovascular space invasion (LVI) (p=3.2E-05, 0.00026, 0.0037, and 0.049; Table 4), while high PD-L1 expression in TICs was associated with non-endometrioid histology, non-G1, deep myometrial invasion, positive LVI, and advanced FIGO stage (p=0.0089, 0.018, 0.0044, 0.00026, and 0.014; Table 4). High density of PD-1⁺ TICs was associated with non-endometrioid histology, non-G1, positive LVI, and MSI (p=0.0086, 1.1E-05, 0.0047, and 0.0015; Table 4). High VEGF expression in TCs was associated with deep myometrial invasion, non-stage I, and advanced stage (p=0.00051, 0.0015, and 0.024; Table 4). High density of CD4⁺ TICs was significantly associated with endometrioid

Zhang S, et al. BMC Cancer. 2020;20:127

histology and superficial myometrial invasion (p=0.033 and 0.00044; Table 4), while high density of CD8⁺ TICs was associated with MSI (p=0.012; Table 4). High density of CD68⁺ TICs showed no significant association with clinicopathologic parameters (Table 4).

	Zhang S, et al. BMC Cancer. 2020;20:127								27												

Thirdly, the patient OS was compared according to the IHC evaluations. Patients with TCs expressing high PD-L1 showed better OS than those with low PD-L1 expression (p=0.004; Fig. 3A), while conversely patients with TICs expressing high PD-L1 showed worse OS than those with low PD-L1 expression (p=0.02; Fig. 3B). High densities of CD4⁺ TICs and CD8⁺ TICs both correlated with better OS (p=0.0008 and 0.04; Fig. 3E

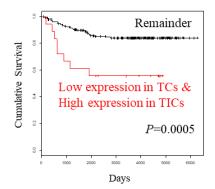

and F). As for PD-1⁺ TICs, VEGF in TCs, and CD68⁺ TICs, the OS showed no significant difference (p=0.1, 0.06, and 0.2; Fig. 3C, D, and G). The OS according to MSI/MSS showed no difference (p=0.9; Fig. 3H).

Fig. 3. Kaplan-Meier curves for overall survival according to TME protein expressions in endometrial carcinomas.[15]

I PD-L1 in TCs and TICs

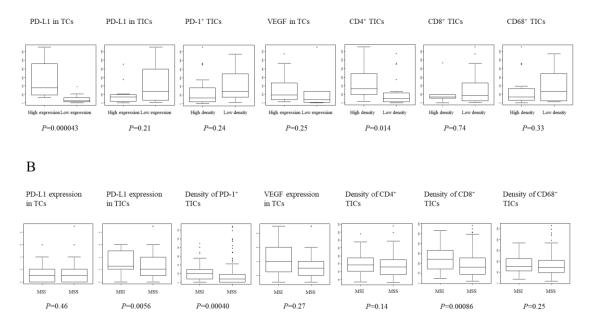

Zhang S, et al. BMC Cancer. 2020;20:127

A, patients with TCs expressing high PD-L1 (n=74) vs. low PD-L1 (n=147); *B*, patients with TICs expressing high PD-L1 (n=36) vs. low PD-L1 (n=185); *C*, patients with PD-1⁺ TICs of high density (n=81) vs. low density (n=140); *D*, patients with TCs expressing high VEGF (n=151) vs. low VEGF (n=70); *E*, patients with CD4⁺ TICs of high density (n=92) vs. low density (n=129); *F*, patients with CD8⁺ TICs of high density (n=124) vs. low density (n=97); *G*, patients with CD68⁺ TICs of high density (n=105) vs. low density (n=116); *H*, patients with MSI tumor (n=48) vs. MSS tumor (n=173); *I*, patients with TCs expressing low PD-L1 and TICs expressing high PD-L1 (n=18) vs. the remaining patients (n=203).

Next, the associations between TFI after primary adjuvant chemotherapy and the TME protein expressions were examined. High PD-L1 expression in TCs and high density of $CD4^+$ TICs were both associated with longer TFI (p=0.000043 and 0.014; Fig. 4A). We further examined the relationships between MSI status and the TME protein expressions. High PD-L1 expression in TICs and high densities of PD-1⁺ TICs and CD8⁺ TICs were associated with MSI (p=0.0056, 0.00040, and 0.00086; Fig. 4B).

Fig. 4. [15]

А

A, Comparison of treatment-free interval (days) between patients with TCs expressing high PD-L1 (n=17) *vs.* low PD-L1 (n=16), those with TICs expressing high PD-L1 (n=13) *vs.* low PD-L1 (n=20), those with PD-1⁺ TICs of high density (n=24) *vs.* low density (n=9), and those with TCs expressing high VEGF (n=27) *vs.* low VEGF (n=6), those with CD4⁺ TICs of high density (n=13) *vs.* low density (n=20), those with CD8⁺ TICs of high density (n=5) *vs.* low density (n=28), and those with CD68⁺ TICs of high density (n=24) *vs.* low density (n=9).

B, Comparison between patients with MSS tumor (n=173) *vs.* MSI tumor (n=48) of IHC scores of PD-L1 expression in TCs, IHC scores of PD-L1 expression in TICs, density of PD-1⁺ TICs, IHC scores of VEGF expression in TCs, density of CD4⁺ TICs, density of CD8⁺ TICs, and density of CD68⁺ TICs.

Zhang S, et al. BMC Cancer. 2020;20:127

Lastly, we conducted univariate and multivariate analyses of prognostic factors for OS. In the univariate analysis, high PD-L1 expression in TICs, older age (>60), advanced FIGO stage, non-endometrioid histology, deep myometrial invasion (>1/2), and positive LVI were found to be significant for worse OS (p=0.023, 0.0017, 2.0E-09, 1.9E-07, 6.4E-06, and 0.00011; Table 5), while high PD-L1 expression in TCs and high density of CD4⁺ TICs were significant for better OS (p=0.0050 and 0.0015; Table 5). Subsequent multivariate analysis revealed that high PD-L1 expression in TCs, high density of CD4⁺ TICs, advanced stage, non-endometrioid histology, and positive LVI were significant and independent for OS (p=0.014, 0.0025, 0.000042, 0.0031, and 0.028; Table 5).

		Univariate			Multivariate	
	HR	95% CI	P -value	HR	95% CI	P-value
High PD-L1 in TCs	0.40	0.21-0.76	0.0050	0.43	0.22-0.85	0.014

4. DISCUSSION

Our survival analyses exhibited that high PD-L1 expression in TCs was associated with better OS, while conversely high PD-L1 expression in TICs was associated with worse OS (Fig. 3A, B, Table 5). Besides, high PD-L1 expression in TICs showed an inverse correlation with high PD-L1 expression in TCs (Table 3). These findings indicate that PD-L1 expression in TCs and that in TICs seem contrary to each other. PD-L1 expressed on the surface of TCs is supposed to bind to PD-1 receptor on immune cells and to induce adaptive immune resistance. Our above observations may be explicable if some proportion of expressed PD-L1 could move between the surface of TCs and the surface of TICs so that the PD-L1 bound to PD-1 on the surface of TICs may induce adaptive immune resistance leading to poor survival, while the PD-L1 remaining on the surface of TCs may not. This hypothesis may be supported by the published findings that, in addition to tissue PD-L1, there also exist circulating PD-L1 such as exosomal PD-L1[19, 20] and soluble PD-L1.[21, 22] However, further molecular and clinical investigations are essential to verify our observation and to elucidate the mechanism underlying them.

High PD-L1 expression in TICs was associated with MSI (Fig. 4B), and with high density of CD8⁺ TICs and CD68⁺ TICs (Table 3), suggesting that PD-L1-induced adaptive immune resistance may involve MSI, killer T cells, and TAMs, as CD8 and CD68 are markers for killer T cells and TAMs, respectively. MSI is known to cause hypermutation leading to increased burden of tumor antigens, which induces increased immune response.[13] Increased immune response may induce PD-1/PD-L1-mediated

adaptive immune resistance, which will lead to aggressive tumor phenotype and poor prognosis. Indeed, our analyses of the relationships between the TME protein expressions and clinicopathologic parameters exhibited that high PD-L1 expression in TICs was associated with non-endometrioid histology, non-G1, deep myometrial invasion, positive LVI, and advanced FIGO stage (Table 4), and our survival analysis demonstrated that high PD-L1 expression in TICs was associated with unfavorable OS (Fig. 3B). Taken together, these findings suggest that PD-L1 expression of TICs may be a biomarker for the T cell-inflamed tumor phenotype.[23] Clinical response to anti-PD-1 monoclonal antibody was reported to occur almost exclusively in patients with pre-existing T cell infiltrates in the region of PD-L1 upregulation.[7, 24] Following anti-PD-1 administration, these CD8⁺ T cells seemed to proliferate and expand to penetrate throughout the tumor, which correlated with tumor regression.[7] Altogether, our findings implicate that anti-PD-1/PD-L1 therapy may improve the unfavorable survival of the subset of endometrial cancers with TICs expressing high PD-L1.

Moreover, in the analysis of the associations between the TME protein expressions and TFI after primary adjuvant chemotherapy, high PD-L1 expression in TCs indicated a longer TFI (Fig. 4A), suggesting that prognostic impact of PD-L1 expression may be mediated by affected chemosensitivity, as TFI reportedly correlates with response to chemotherapy for recurrence and/or survival after recurrence in endometrial cancer[25-27]. This hypothesis may be supported by the published findings where upregulation of the PD-1/PD-L1 axis confers chemoresistance in some types of tumor.[28-30] Accordingly, our findings further suggest that anti-PD-1/PD-L1 therapy may attenuate chemoresistance in the patients with TICs expressing high PD-L1.

In the univariate and multivariate analyses of prognostic factors, besides high PD-L1 expression in TCs, high density of CD4⁺ TICs was found to be significant and independent for favorable OS (Table 5), being consistent with previous publications where high infiltration of CD4⁺ TILs was reported to be a favorable prognostic factor for some types of malignancy.[31-33] Besides, high density of CD4⁺ TICs was found to be associated with longer TFI (Fig. 4A), suggesting that helper T cells also may affect prognosis through involving chemosensitivity. The proliferation and differentiation into regulatory T cells of CD4⁺ T cells is reported to be manipulated by retinoic acid [34], STAT3 silencing [35], and DNGR-1 targeting [36], raising their therapeutic possibility. Further basic and clinical studies are warranted to verify our proposal.

The KEYNOTE-028 phase I study evaluated the safety and efficacy of pembrolizumab, an anti-PD-1 monoclonal antibody, in patients with PD-L1-positive advanced solid tumors.[37] Pembrolizumab demonstrated a favorable safety profile and durable antitumor activity in a subgroup of patients with heavily pretreated advanced PD-L1-positive endometrial cancer.[37] Currently, many phase II/III clinical trials of anti-PD-1/PD-L1 therapy in endometrial cancers are ongoing. Our above findings indicate that anti-PD1/PD-L1 therapies combined with conventional chemotherapeutics may be beneficial for the patients with poor prognosis due to high PD-L1 expression in TICs through improving chemosensitivity.

There exist only few reports on prognostic significances of the TME proteins in endometrial cancer so far (Table 6). Regarding PD-L1 expression and survival, Kim et al. have recently reported on 183 primary endometrial cancers that high PD-L1 expression on immune cells was an independent prognostic factor for poor PFS.[38] Ikeda et al. have also reported on 32 endometrioid endometrial cancers that the cases with high PD-L1 mRNA expression in cancer tissues showed significantly longer PFS.[39] Yamashita et al. have recently reported on 149 endometrioid endometrial cancers that high PD-L1 expression in tumor cells was significantly associated with better PFS.[40] These findings are in line with our results that high PD-L1 expression in TCs was associated with better OS (Fig.3A), while high PD-L1 on TICs was associated with worse OS (Fig. 3B). As for CD8 expression and survival, Yamashita et al. have reported that CD8⁺ TILs was significantly associated with better PFS.[40] Ikeda et al.

also reported that high CD8 mRNA expression in tumor tissues was significantly associated with longer PFS.[39] These findings are consistent with our result that high density of CD8⁺ TICs correlated with better OS (Fig. 3F). Bellone et al. have recently reported on 131 endometrial cancers that POLE-mutated tumors were associated with improved PFS and displayed increased numbers of CD4⁺ and CD8⁺ TILs as compared to wild-type POLE tumors, and that PD-1 was overexpressed in TILs from POLE-mutated vs. wild-type-tumors.[41] In our study, MSI was associated with high PD-L1 expression in TICs (Fig. 4B), which was significantly associated with worse OS (Fig. 3B). POLE-mutated endometrial cancers have been reported to be MSS in a couple of studies including this article.[41-43] Therefore, it is plausible that POLE-mutated tumors and MSI tumors may have the opposite prognostic features. As regards the relationship between PD-L1 expression and clinicopathologic features, Mo et al. reported on 75 endometrial cancers that PD-L1 expression in TICs was more frequently found in the moderately and poorly-differentiated tumors and type II than in the type I tumors, [44] being in line with our finding that high PD-L1 expression in TICs was associated with non-endometrioid histology and non-G1 (Table 4). Further studies are warranted to clarify the clinical and prognostic significance of the TME status in endometrial cancer.

Reference	Ν	Median follow-up duration (months)	Results consistent with ours	Results different from ours
Our study	221	132		
Kim et al. Gynecol Oncol (2018)	183	30.3	• High PD-L1 on immune cells was an independent prognostic factor for poor PFS.	• High PD-L1 on tumor cells was not significantly associated with survival.
Yamashita et al. Oncotarget (2018)	149 (Endometrioid only)	38	 High PD-L1 expression in tumor cells was significantly associated with better PFS. CD8⁺ TILs was significantly associated with better PFS. 	
Ikeda et al. Oncol Rep (2017)	32 (Endomerioid only)	Not reported	 High PD-L1 mRNA expression in cancer tissues showed significantly longer PFS. High CD8 mRNA expression in tumor tissues was significantly associated with longer PFS. 	

Table 6. Published survival impact of TME in endometrial cancer.

The present study still contains some limitations. The retrospective study design potentially causes selection biases. The studied sample number is relatively small. The evaluation method for the TME protein expression is mainly based on semi-quantitative analyses. Considering intratumoral heterogeneity may affect our results. Nevertheless, the treatment strategy was almost consistent throughout the study period, and most importantly the follow-up duration was much longer than the former studies (median, 132 *vs.* 30.3-38 months[38, 40]), supporting the validity of our survival data.

For our future experiments, we are planning to perform multi-color immunofluorescence imaging of PD-L1, PD-1, CD8, CD4, and Foxp3 in order to investigate the detailed mechanism of prognostic effect by PD-1/PD-L1, as CD4+Foxp3+ regulatory T cells are supposed to inhibit antitumor immune system.

5. CONCLUSIONS

We have demonstrated here that high PD-L1 in TCs was associated with better OS, while high PD-L1 in TICs was associated with worse OS. High PD-L1 in TICs exhibited associations with high densities of CD8⁺ TILs and CD68⁺ TAMs, and MSI, while high PD-L1 in TCs correlated with longer TFI. High density of CD4⁺ TICs correlated with better OS and longer TFI. Univariate and multivariate analyses exhibited that high PD-L1 in TCs and high density of CD4⁺ TICs were significant and independent prognostic factors for favorable OS. The current findings indicate that PD-L1 and CD4⁺ helper T cells may be reasonable targets for improving survival via enhancing chemosensitivity, providing useful information for combining immunotherapies into the therapeutic strategy for endometrial carcinoma.
