Abstract

Background Alternate-day administration of S-1 is thought to reduce toxicities. This phase II study evaluated S-1 on alternate days combined with bevacizumab as first-line treatment for elderly patients with metastatic colorectal cancer.

Patients and Methods Eligible patients had histologically proven colorectal adenocarcinoma, measurable metastatic lesions, age ≥ 75 years, Eastern Cooperative Oncology Group performance status ≤ 1 , no previous chemotherapy, and refused oxaliplatin- or irinotecan-containing regimens. Patients received 40 mg, 50 mg, or 60 mg (body surface area $\leq 1.25 \text{ m}^2$, >1.25 to $\leq 1.50 \text{ m}^2$, or $>1.50 \text{ m}^2$, respectively) of S-1 twice orally on Sunday, Monday, Wednesday, and Friday every week. Bevacizumab (7.5 mg/kg) was administered every 3 weeks. The primary endpoint was progression-free survival.

Results Of 54 enrolled patients, 50 patients were evaluated for efficacy and 53 for safety. The median age was 79 years (range, 75-88 years). The median progression-free survival was 8.1 months (95% confidence interval, 6.7-9.5 months). The median overall survival was 23.1 months (95% confidence interval, 17.4-28.8 months). The response rate was 44% (95% confidence interval, 30.2-57.8%), and the disease control rate was 88% (95% confidence interval, 79.0-97.0%). Grade 3 or higher hematologic, non-hematologic, and bevacizumab-related adverse events occurred in 9%, 11%, and 25% of patients,

1
2
3 respectively. The most common grade 3 and 4 treatment-related adverse events were hypertension (11%),
4
5
6
7 nausea (6%), fatigue (6%), anemia (6%), and proteinuria (6%). Only 6 patients discontinued treatment
8
9
10 due to adverse events.
11
12

13
14 **Conclusion** S-1 on alternate days combined with bevacizumab showed better tolerability and comparable
15
16
17 survival compared with the results of similar studies.

Introduction

Colorectal cancer (CRC) is a common cause of cancer-related death worldwide [1,2]. In Japan, more than 70% of mortality occurs in patients over 75 years old. The proportion and number of elderly patients with metastatic CRC (mCRC) who are treated with chemotherapy is increasing [2].

The first-line standard treatment for patients with mCRC is doublet (fluoropyrimidine [FP] plus oxaliplatin or irinotecan) chemotherapy combined with a molecular targeted agent (bevacizumab, cetuximab, or panitumumab) [3-5]. However, elderly patients often cannot tolerate this combination chemotherapy because of emerging adverse events, comorbidity, and decreased organ function. Therefore, FP combined with bevacizumab has been recognized as a favorable treatment for elderly patients with mCRC [6-8].

S-1, an oral FP, showed promising results in two phase II trials for chemo-naïve patients with mCRC [9,10]. The standard treatment schedule of S-1 was twice daily administration for 4 weeks followed by 2 weeks' rest. To increase safety, S-1 on alternate days was studied as a new administration schedule, utilizing the difference in cell cycles between normal gastrointestinal epithelium and tumor cells: the normal cell cycle is approximately 0.5 to 1.5 days, whereas the tumor cell cycle ranges from 3 to 5 days, and duration of the S-phase, where 5-fluorouracil is most active, is a few days in most cancer

1
2
3 cells [11-15]. In a retrospective study, this alternate-day S-1 schedule was studied in 92 patients with
4
5
6
7 advanced gastric cancer. Grade 2 and higher non-hematologic toxicities were observed in only 3% of the
8
9
10 patients, and the median time to treatment failure and median overall survival (OS) were 6 and 11
11
12
13 months, respectively, which was similar to those in a previous study of the standard S-1 treatment
14
15
16
17 schedule [16].

31 ***Material and Methods***

32 33 34 35 **Study design**

36
37
38 This study was designed as a prospective, open-labeled, single-arm, multicenter phase II trial (J-SAVER:
39
40
41
42 Joint study of S-1 on Alternate days combined with beVacizumab in Elderly patients with metastatic
43
44
45 coloRectal cancer) by the nonprofit organization Tsukuba Cancer Clinical Trial Group and the Shikoku
46
47
48
49 Gastrointestinal Oncology Study Group in Japan [17]. The study was conducted according to the
50
51
52
53 Declaration of Helsinki/Tokyo and the Japanese Clinical Research Guidelines. The study protocol was
54
55
56
57 approved by the ethics committee of each participating institution. Informed consent forms were signed
58
59
60
61
62
63
64
65

1
2
3 by all patients before study entry. The study treatment was started within 14 days from the date of
4
5
6
7 enrollment. The study protocol was registered at the University Hospital Medical Information Network,
8
9
10 UMIN000010402, on April 2, 2013.

17 **Patients**

18
19
20
21 The main inclusion criteria were as follows: pathologically confirmed colorectal adenocarcinoma; age
22
23
24 ≥ 75 years; Eastern Cooperative Oncology Group performance status (ECOG PS) ≤ 1 ; no previous
25
26
27
28 chemotherapy except for adjuvant chemotherapy with FP completed 6 months or more before enrollment;
29
30
31 presence of measurable lesions as defined by the Response Evaluation Criteria in Solid Tumors
32
33
34 (RECIST) version 1.1; and adequate bone marrow, hepatic, and renal function. The main exclusion
35
36
37
38 criteria included inability to take oral medication, uncontrolled hypertension, previous radiation therapy
39
40
41
42 over the pelvic cavity, urine protein $\geq +2$ with a stick kit for routine urinary analyses, and history of severe
43
44
45 thrombosis. The details of the eligibility criteria have been previously reported [17]. *RAS* mutation was
46
47
48
49 examined in paraffin-embedded tumor tissues at individual institutions using validated methods approved
50
51
52
53 by the Japanese Ministry of Labor and Welfare [18,19]. In Japan, *RAS* mutation analysis was performed
54
55
56
57

65

at only *KRAS* exon 2 (codons 12 and 13) until Apr 2015, and expanded to *KRAS/NRAS* exons 2, 3, and 4 thereafter.

Treatment schedule

Patients received 40 mg (body surface area [BSA] $\leq 1.25 \text{ m}^2$), 50 mg (BSA > 1.25 to $\leq 1.50 \text{ m}^2$), or 60 mg (BSA $> 1.50 \text{ m}^2$) of S-1 orally, twice a day, on Sunday, Monday, Wednesday, and Friday every week. The protocol treatment was repeated until tumor progression, development of severe adverse events, or patient refusal. Bevacizumab was administered at 7.5 mg/kg every 3 weeks (Fig. 1). S-1 was postponed if the blood neutrophil count was $< 1,000/\text{mm}^3$ or the platelet count was $< 75,000/\text{mm}^3$. Re-initiation of S-1 required non-hematological toxicities, including infection, diarrhea, oral mucositis, nausea, or vomiting, to be grade ≤ 1 . S-1 was discontinued in cases of serum creatinine level $\geq 1.2 \text{ mg/dL}$, serum total bilirubin level $\geq 2.5 \text{ mg/dL}$, serum aspartic aminotransferase (AST) level or serum alanine aminotransferase (ALT) level $> 100 \text{ IU}$ ($> 200 \text{ IU}$ in patients with liver metastasis), and grade 2 or higher diarrhea, mucositis, nausea, or vomiting. S-1 was re-initiated at a reduced dose if patients recovered from these adverse events. The dosage of S-1 was reduced by 20% in patients who experienced a neutrophil count $< 500/\text{mm}^3$, platelet count $< 50,000/\text{mm}^3$, serum creatinine level $\geq 1.5 \text{ mg/dL}$, serum total bilirubin level \geq

1
2
3 4.0 mg/dL, serum AST or ALT level > 200 IU, or grade 3 or higher diarrhea, mucositis, nausea, or
4
5
6
7 vomiting. In addition, dose reduction and treatment delay by physician's determination were allowed,
8
9
10 taking into account patient safety.

16

17 **Assessment**

18
19
20
21 Adverse events during treatment were assessed according to the Common Terminology Criteria for
22
23
24 Adverse Events version 4.0. Blood tests included complete blood cell counts, liver and renal function
25
26
27 tests, and tumor markers (carcinoembryonic antigen and carbohydrate antigen 19-9), and the urine test
28
29
30 included a semi-quantitative protein test. Observation, assessment, and blood and urinary tests were
31
32
33 performed every week until the second administration of bevacizumab, and every 3 weeks on the day of
34
35
36 bevacizumab administration thereafter. Tumor assessments were performed according to RECIST version
37
38
39
40
41
42 1.1. Computed tomography or magnetic resonance imaging was performed every 8 weeks for evaluation
43
44
45 of tumors. The relative dose intensity (RDI) of S-1 and bevacizumab were calculated as the actual total
46
47
48 dose divided by the pre-planned total dose during study treatment. A dedicated schedule calendar was
49
50
51
52
53 used by patients or family members to record whether the patient orally took S-1.
54
55

63
64
65

Statistical analysis

The primary endpoint was progression-free survival (PFS). The secondary endpoints were safety, response rate, and OS. In a previous phase II study of standard S-1 monotherapy for patients with mCRC, the median PFS was 5.1 months [9,10]. The median PFS of 5-fluorouracil and leucovorin plus bevacizumab therapy was 3.7 months longer than that of 5-fluorouracil and leucovorin monotherapy in a randomized phase II study [6]. Therefore, we set the expected median PFS at 8.5 months and the minimum efficacy threshold at 5.0 months. The required sample size was calculated as 50 patients, with a two-sided type I error of 0.10 and a power of $\geq 80\%$. As post-hoc analyses, PFS and OS were evaluated according to *RAS* mutation status: exon 2 (codons 12 and 13), exon 3 (codons 59 and 61), and exon 4 (codons 117 and 146) of *KRAS* and *NRAS*. PFS was defined as the time from enrollment to disease progression or death from any cause. OS was defined as the time from enrollment to death from any cause. The PFS and OS with 95% confidence interval (CI) were estimated using the Kaplan-Meier method. The response rate with 95% CI was calculated using normal approximation based on the best response by the investigator. P value of $< .05$ was considered to indicate statistical significance. All analyses were performed using SPSS software, version 22.0 (IBM Japan, Tokyo).

Results

Patients

Fifty-four patients were enrolled from April 2013 to October 2016. Among them, 50 and 53 patients were evaluated for efficacy and safety, respectively. The flow chart of patient selection is shown in Fig. 2.

The median patient age was 79 years (range, 75-88 years) (Table 1). The ECOG PS was 0 in 28 patients (56%) and 1 in 22 patients (44%). Primary tumors were located in the cecum, ascending colon, and transverse colon in 15 patients (30%) (right side), and in the descending colon, sigmoid colon, and rectum in 35 patients (70%) (left side). Half of the patients had one metastatic site. The tumor *RAS* mutation status was examined in 44 patients (21 wild-type and 23 mutant *RAS*).

Efficacy

The median follow-up times for PFS and OS were 34.5 and 44.9 months, respectively. PFS events occurred in 40 patients (80%). The median PFS was 8.1 months (95% CI, 6.7-9.5 months) (Fig. 3a). Thirty-nine patients (78%) died. The median OS was 23.1 months (95% CI, 17.4-28.8 months) (Fig. 3b). One patient showed complete response, and 21 had partial responses. The response rate was 44% (95% CI, 30.2-57.8%), and the disease control rate was 88% (95% CI, 79.0-97.0%). Waterfall plots of the best

responses are shown in Fig. 4. Tumor shrinkage was observed in 37 patients (74%). Four patients showed 100% tumor regression, but 2 patients with partial response had non-measurable lesions and 1 patient with stable disease had a new lesion when the measurable lesions had disappeared.

In post-hoc survival analyses according to *RAS* mutation status, the median PFS were 7.9 months (95% CI, 7.1-8.7 months) for patients with wild-type *RAS* and 7.8 months (95% CI, 6.6-8.9 months) for those with mutant *RAS* ($P = 0.80$). The median OS were 24.2 months (95% CI, 17.3-31.0 months) for patients with wild-type *RAS* and 23.8 months (95% CI, 8.9-38.7 months) for those with mutant *RAS* ($P = 0.80$).

Safety

The adverse events are summarized in Table 2. Grade 3 or higher hematologic, non-hematologic, and bevacizumab-related adverse events were observed in 5 (9%), 6 (11%), and 13 (25%) patients, respectively. The most common grade 3 and 4 treatment-related adverse events were hypertension (11%), anemia (6%), nausea (6%), fatigue (6%), and proteinuria (6%). Treatment-related death caused by cerebral infarction was observed in one patient. The patient experienced several grade 2 non-hematologic

1
2
3 toxicities, and the dose of S-1 was reduced to 60% of the initial dose. He developed cerebral infarction
4
5
6
7 after 13 doses of bevacizumab and died 12 months after the start of the study treatment.
8
9

10 The median duration of treatment was 7.8 months (range, 0.5-31.5 months). The median
11
12
13 cumulative dose of S-1 was 13,060 mg (range, 280-54,250 mg) and that of bevacizumab was 3,980 mg
14
15
16
17 (range, 270-24,910 mg). Seventeen patients (32%) required dose reduction or treatment delay of S-1, and
18
19
20
21 14 patients (26%) required treatment delay of bevacizumab. The median RDI was 92% (range, 20-100%)
22
23
24 for S-1 and 89% (range, 34-100%) for bevacizumab. The median RDI according to the original S-1
25
26
27 treatment schedule was 79% (range, 18-84%).
28
29
30

31 **Subsequent treatments** 32 33

34
35 Among the patients who received study treatment ($n = 53$), discontinuation of the study
36
37
38 treatment was reported in 50 patients (94%), and the reason for discontinuation was disease progression
39
40
41 in 40 patients (75%), adverse events in 6 patients (11%) (1 patient each: grade 2 anorexia, grade 2
42
43
44 anorexia and fatigue, grade 3 anorexia, grade 3 wound dehiscence, grade 3 colonic perforation, and grade
45
46
47 5 cerebral infarction), withdrawal of consent in 1 patient, and other in 3 patients (1 patient each: sepsis
48
49
50 due to aspiration pneumonia, dementia, and unknown) (Table 3). After discontinuation of the study
51
52
53
54
55 treatment, 14 patients (26%) received best supportive care alone, and 33 patients (62%) were treated with
56
57
58
59
60
61
62
63
64
65

any chemotherapy, including oxaliplatin- and irinotecan-containing therapy ($n = 14$ and 8 , respectively).

In 22 patients who received oxaliplatin- or irinotecan- containing therapy, the median age was 78 years

(range, 75-86 years), and 14 patients (64%) had an ECOG PS of 0. No complete response was observed,

and 10 patients achieved partial response (45%). The incidences of grade 3 or higher hematologic-, non-

hematologic-, and bevacizumab-related toxicities were 5%, 9%, and 14%, respectively. The median RDIs

were 95% (range, 46-98%) for S-1 and 93% (34-100%) for bevacizumab.

Discussion

We studied S-1 administration on alternate days combined with bevacizumab as first-line treatment for

elderly (≥ 75 years) patients with mCRC in a multicenter phase II trial, and showed modest activity and

well-tolerated toxicities, while keeping dose intensities of S-1 and bevacizumab as high as approximately

90%.

The main results reported in similar studies of elderly patients with mCRC are summarized in

Table 4. The PFS in our study was comparable to those in previous studies of other FPs combined with

bevacizumab [7,20-22]. The dose intensity of S-1 on alternate days corresponded with approximately

86% of the standard daily S-1 dose, and the actual median dose in alternate-day S-1 administration was

1
2
3 79% of the standard dose in the present study. In general, FP plus bevacizumab has been reported to be
4
5
6
7 well tolerated in elderly patients. However, the incidence of grade 3 or higher toxicities was reported as
8
9
10 30% in two studies [7,23]. Even in other studies in which grade 3 or higher toxicities were observed in
11
12
13 less than 10% of patients, treatment was discontinued due to relatively mild to moderate toxicities in
14
15
16 approximately 30% of patients [20,22]. In contrast, the incidence of grade 3 or higher toxicities in our
17
18
19 study was low, as expected, and only 11% of patients discontinued treatment due to toxicities. In
20
21
22
23
24 addition, incidences of lacrimal disorder and skin disorder, including hand-foot skin reaction, were lower
25
26
27 than those in previous studies in elderly patients [7,22]. This suggests that an alternate-day S-1 schedule
28
29
30
31 had better tolerability than previously reported FP plus bevacizumab regimens.
32
33

34
35 Recently, two randomized phase II studies of alternate-day S-1 therapy were reported in
36
37
38 advanced gastric and pancreatic cancers [24,25]. This regimen was inferior in efficacy to the standard
39
40
41 daily S-1 regimen, although adverse events were mild. One plausible reason for these negative results is
42
43
44 the insufficient anti-tumor activity of S-1 due to underdosing in the alternate-day schedule. Nevertheless,
45
46
47 these results in advanced gastric and pancreatic cancer do not undermine our favorable results in elderly
48
49
50 mCRC patients. These studies included younger patients who could have tolerated the standard daily S-1
51
52
53 regimen, and elderly patients accounted for less than half of the population. Starting with a reduced dose
54
55
56
57
58
59
60
61
62
63
64
65

of FP was often adopted in previous studies for elderly patients with mCRC [6,20,21,23]. In a phase II study, aggressive dose modification of capecitabine plus bevacizumab provided rather favorable results in elderly mCRC patients [26]. In the FOCUS2 trial for elderly/frail patients in which FP alone or FP combined with oxaliplatin was started at a reduced dose, only 37% of patients could tolerate a dose increased to the standard level. In contrast, doublet regimens have been reported to demonstrate promising activity and tolerability in elderly patients with mCRC [23,27-30]. Although doublet regimens should be considered first for elderly patients, not all elderly patients can continue those treatments because of toxicities, and a considerable number of patients actually refuse them to avoid treatment-related toxicities. Our regimen may be a good option as an introductory treatment for such patients.

Our study suggested that *RAS* mutation had no impact on PFS in patients administered FP plus bevacizumab, similar to the results of a previous report [31]. Anti-epidermal growth factor receptor (EGFR) antibody-containing therapy is recommended for mCRC patients with wild-type *RAS*, and bevacizumab-containing therapy is an optional treatment. In a previous report, the median PFS was 6.4 months in elderly patients with wild-type *KRAS* and 8.4 months in those with wild-type *KRAS/NRAS* [32-34]. The median PFS in our patients with wild-type *KRAS* or *KRAS/NRAS* was similar to these previously

1
2
3 reported values. If elderly patients want to avoid anti-EGFR antibody-related skin toxicities, our regimen
4
5
6
7 would be a good substitute.
8
9

10 Elderly patients are extremely diverse. Therefore, the present study had several limitations.
11

12
13 The tolerability of chemotherapy for elderly patients is often associated with polypharmacy, comorbidity,
14
15
16 renal function, psychological state, and family support [35,36]. We could not assess these important
17
18
19 factors; however, they are very difficult to investigate in all clinical trials. Geriatric function assessment
20
21
22 was lacking in our study. Various tools have been attempted for geriatric assessment in oncology trials,
23
24
25 but a convenient, useful, and validated tool has not yet been established [35,36]. That the adherence rate
26
27
28 of oral anti-cancer drugs is lower than that of intravenous anti-cancer drugs also needs to be considered
29
30
31 [37]. In order to maintain the dose intensity of S-1 in this study, we asked the patients and their family
32
33
34 members to record the day and dose of orally administered S-1 using a dedicated schedule calendar, and
35
36
37
38
39
40
41 we checked the adherence.
42
43
44

45 In conclusion, alternate-day S-1 combined with bevacizumab was well tolerated and
46
47
48 maintained activity in elderly patients (≥ 75 years old) with mCRC and might be recommended as an
49
50
51 optional treatment. Further studies are needed to evaluate the influence of different FP toxicities on
52
53
54
55
56
57
58
59
60
61
62
63
64
65

patients' quality of life and to find the optimal treatment for individual patients based on geriatric
assessment.

We are grateful to Kentaro Yamazaki, Takako E. Nakajima, and Takehiro Oikawa for their important contributions to this study as part of the Data and Safety Monitoring Committee and Miss Mizuki Aida for data management. The participating investigators are as follows: T. Masuishi and T. Eto (Tsuchiura Kyodo General Hospital); S. Yoshida, Y. Ito, and M. Shimoyamada (National Hospital Organization Mito Medical Center); T. Murashita (Ryugasaki Saiseikai Hospital); H. Satake (Kobe City Medical Center General Hospital); M. Chikakiyo (Tokushima Prefecture Naruto Hospital); T. Fujita and S. Mori (JCHO Ritsurin Hospital), A. Soeda and M. Kobayashi (Tsukuba Memorial Hospital), J. Higashijima and T. Nakao (Tokushima University); M. Inukai and Y. Suzuki (Kagawa University), M. Goto (Ibaraki Prefectural Central Hospital and Cancer Center). This work is supported by the NPO Tsukuba Cancer Clinical Trial Group. We would like to thank Editage (www.editage.jp) for English language editing.
